Introduction to the LANAP protocol for the treatment of periodontitis

Author: Robert H. Gregg II, DDS

The breakthrough LANAP® protocol offers many advantages over conventional flap periodontal surgery or scaling and root planing for the treatment of periodontitis. This no-cut, no-sew technique is bringing revolutionary outcomes into the treatment rooms of general dentists and periodontists alike, allowing the profession to battle against a disease that threatens the health of more than 80 percent of Americans. This overview explains what the LANAP procedure is, how it works and what clinical trials are showing about the exciting results this strict protocol can achieve for patients with gingivitis, "garden variety" periodontitis — and even the most extremely severe forms of gum disease.

Most Americans — about 80 percent — suffer with gum disease on some level, according to the U.S. surgeon general. Michael Newman, DDS, PhD, says that only 3 percent of the 100 million-plus Americans with moderate to severe periodontal disease are treated each year, which means an increasing number of worsening cases appear in general dental practices across the country every day.1 The growing threat requires a greater number of general dentists to take the lead in properly performing a periodontal probing exam. Still, for many offices, the challenge lies in persuading the patient to seek treatment via referral to a periodontist.

A growing number of general practitioners have reached a frustration threshold, seeing one patient after another who either continues with poor gum health or seeks treatment from a periodontist and achieves results that ultimately leave much to be desired. Some of these dentists have discovered a treatment protocol that allows them to take action and provide patients improved care — without even referring them out of the practice. The treatment is achieving unsurpassed results not otherwise attainable with conventional techniques.

Widely known to be closely linked with heart disease and strokes, periodontitis has now been fingered as the cause in a full-term baby’s death.2 It is believed that the mother’s gum disease introduced fatal bacteria to her womb. In an age of burgeoning technology, the news stories linking gum disease to more disastrous results are inevitable. As the dangerous consequences of gum disease become increasingly clear, more dental clinicians must take the reins in educating patients and ensuring their successful treatment.

Dental practitioners have used free-running (FR) pulsed Nd:YAG lasers for longer than 20 years, but only recently has the laser been combined with a specific, successful protocol and research-proven operating parameters to achieve FDA clearance and a track record of success in university-based clinical studies for its efficacy at “cementum-mediated new PDL attachment to the tooth root surface in the absence of long junctional epithelium.”3,4 The protocol has shown consistent probe depth reduction, histological and clinical new attachment, and radiographic bone growth for periodontally involved teeth with no elevation of the periosteum and minimal patient discomfort.5-7

Its greatest potential may lie in patients’ willingness to accept treatment and comply. With 97 percent refusing current protocols, a no-cut, no-sew solution has meant a flock of new patients willing to seek treatment for their gum disease from those dentists who choose to offer the LANAP protocol.

What is the LANAP protocol?

The procedure combines the PerioLase MVP-7 Free-Running (FR) pulsed Nd:YAG laser with a strict, specific, research-proven protocol that has achieved FDA clearance for the treatment of all forms of gum...
disease — from early detection to so-called “hopeless” teeth. The breakthrough is called laser assisted new attachment procedure (LANAP), and it has left a trail of healthy patients in its wake for the inventors of the protocol, Dr. Robert H. Gregg II and Dr. Delwin K. McCarthy, as well as more than 1,000 dentists and specialists who have learned the procedure from the Institute for Advanced Laser Dentistry (IALD).

Gregg and McCarthy pioneered the use of the FR pulsed Nd:YAG laser in treating gum disease in the 1990s. They were astounded by their ability to re-generate bone growth (routine 50 percent defect fill) and stimulate new attachment for their patients with severe gum disease. The results were too good to keep to themselves. The pair continued to fine-tune the procedure after patenting it so they could share it with peers and envision a goal for the new gold standard for the treatment of gum disease across the country.

_The LANAP treatment protocol_

Designed and refined for 10 years, the LANAP technique’s specific clinical steps must be performed properly and in precise order to achieve consistent positive outcomes. The key steps, in order, make up the patented portion of the technique and are the crux of why the LANAP protocol is so successful. The procedure may be performed in all four quadrants in a single appointment, but for patient comfort and case control, laser treatment is typically limited to no more than two non-adjacent quadrants per visit, with several days between visits.

First, the patient is profoundly anesthetized with local anesthetic so that the patient’s pocket depths can be probed down to the level of intra-osseous defects (bone sounding). The thin optic fiber is then used parallel to the root surface, to effect the pocket wall. Next, an EMS ultrasonic scaler removes calcified plaque and calculus adherent to the root surface. The first pass with the laser, called laser troughing, is accomplished with the short duration pulse. The FR pulsed Nd:YAG laser is used to achieve optimal reduction of microbiotic pathogens (antisepsis) within the periodontal sulcus and surrounding tissues. Perio pathogens and pathologic proteins are selectively destroyed by the laser’s light energy, providing an antiseptic surgical environment that allows healing following the laser hemostasis step.8–15

The technique uses selective photothermolysis to remove the diseased, infected and inflamed pocket epithelium while preserving healthy connective tissue, literally separating the tissue layers at the level of the rete pegs and ridges.8–11 The practitioner is able to achieve both tissue ablation and antiseptic hemostasis with extreme precision by varying the laser’s energy density, pulse duration and rate of repetition. The laser assists in the destruction of perio pathogens while preserving the healthy tissue, allowing for less post-operative discomfort and a much shorter post-surgical recovery perception for the patient.

At this point, a second pass is completed to finish debridging the pocket and achieve hemostasis with a thermal fibrin clot. Gingival tissue is compressed against the root surface as necessary to close the pocket and aid with formation and stabilization of the fibrin clot. No sutures or surgical glue is needed. Mobile teeth above class II mobility are splinted. Occlusal adjustments are performed to remove interferences, minimize trauma, and provide balance to long axis forces and are considered an essential component of the LANAP protocol.

Finally, post-operative instructions specific to the LANAP protocol, diet guidelines and oral hygiene instructions are explained and their importance is stressed, and continued periodontal maintenance is scheduled. Patients are monitored at one week, 30 days and then every three months for periodontal maintenance. No subsequent probing is performed for at least six months to a year, to allow sufficient healing time for the cementum-fiber PDL interface.

Harnessing the LANAP protocol’s results

The availability of a procedure that eliminates cutting and sewing without gum recession is changing the standard of care for periodontitis treatment. Not only is there a treatment protocol that is universally accepted by patients, but it also represents an option that includes both specialists and general practitioners in the solution. A general practitioner who may be reluctant to perform invasive surgery may welcome the opportunity to treat such an overwhelming health issue without referring patients elsewhere. Alternatively, the LANAP protocol practiced by periodontic specialists, becomes a more attractive referral for general practitioners and their patients.

Those who choose to embrace the LANAP protocol do so with a support system in place. Clinicians are required to undergo extensive training and adhere to the protocols that have proven successful before performing the LANAP technique. Millennium Dental Technologies, the manufacturer of the PerioLase MVP-7, requires clinicians satisfactorily complete a three-day lecture course and live, hands-on patient training. Not only is there a treatment protocol that is universally accepted by patients, but it also represents an option that includes both specialists and general practitioners in the solution. A general practitioner who may be reluctant to perform invasive surgery may welcome the opportunity to treat such an overwhelming health issue without referring patients elsewhere. Alternatively, the LANAP protocol practiced by periodontic specialists, becomes a more attractive referral for general practitioners and their patients.
The science behind the LANAP protocol

Early LANAP protocol research showed consistent mean pocket depth reduction (nearly 50 percent) and improved bone density (38 percent) in an eight-year retrospective study of the protocol's earliest clinical results. The Emago imaging system demonstrated that 100 percent of these cases showed bone density increases. The procedure has also proven effective at reducing pocket depth without gingival recession over a six-month period.16,17

In the fourth-largest human histological study in the perio regeneration literature (with a control group), the LANAP protocol using the PerioLase MPV-7 was compared to a blinded examiner (clinical) conventional scaling and root planing without laser assistance. Twelve teeth were removed en bloc and examined by a blinded histologist. When the blinded code was broken, all teeth treated with the LANAP protocol demonstrated 100 percent cementum-mediated new periodontal ligament attachment to the previously periodontally affected tooth roots in all six of the LANAP-treated teeth and in the absence of long junctional epithelium.8,11 These results are unique in the perio literature.

Given its unique, predictably regenerative results, it should come as no surprise that the LANAP protocol has inspired its share of imitators. As yet, those copycat protocols have no science to support their continued use. The patented LANAP protocol is the only peer-reviewed and FDA-cleared approach that is proven successful at treating mild, moderate and especially severe periodontitis.

LANAP protocol vs. cut-and-sew procedures

The successful treatment of periodontal disease requires thorough debridement of the root surface. Pockets of 5 mm or greater depth make it difficult to remove subgingival plaque and calculus. Surgical intervention allows access and visualization for scaling and root planing in these deep pockets.18 While scalpel surgery can accomplish such access and visualization, it can also result in attachment loss, gingival cratering and gingival recession.19–22 Additionally, the associated pain and discomfort can be deterrents.23

In any case, many general practitioners would never consider performing conventional flap surgery because of its invasive nature.

LANAP treatment, while an exceptional alternative, is not without its drawbacks. The predominant issues involve cost and time. The initial financial outlay for the laser equipment can be cost-prohibitive for some practices. Similarly, dental clinicians must be willing and able to take time away from the office to undergo procedural training and learn LANAP treatment with live patients. Following the training, and as with anything new, there can be a learning curve as clinicians grow comfortable and begin to excel at treating patients with LANAP procedures.

For now, cut-and-sew techniques remain the standard of care and additional study will be required to persuade many professionals that any laser system provides clinical value surpassing scaling and root planing techniques and conventional surgical treatment.24 Cautious experts warn that the improper use of the Nd:YAG laser can have detrimental effects on the root surface ranging from heat cracking to charring, cementum meltdown and crater formation.25 These negative outcomes are not typical with adherence to current LANAP protocols and thus far appear to result from improper laser settings. Studies continue, and most researchers agree that laser or laser-assisted pocket therapy is expected to become a new technical modality in periodontics.26

Robert H. Gregg II, DDS, is a former faculty member at the
UCLA School of Dentistry. He has been using lasers clinically
since August 1990, including C22, free-running pulsed
(FRP) Nd:YAG, both single and variable pulsed; FRP Ho:YAG,
surgical Argon, CW diodes and Er:YAG. He has given
lectures both nationally and internationally on the subject
of clinical laser applications, and he has conducted
seminars for the UCLA Department of Continuing Education.
In addition to authoring several peer-reviewed articles on the
clinical applications of FRP Nd:YAG for endodontic and
periodontal uses, he is an au-
tor of the Curriculum Guide-
lines and Standards for Dental
Laser Education. Gregg has
obtained his membership and
educator’s certification in the
Academy of Laser Dentistry.
He has been appointed as a peer-review member of the
Dentistry Today CE Editorial
Board. He is a co-developer of the FDA-cleared PerioLase
MPV-7 pulsed Nd:YAG laser,
and is a founder of Millennium
Dental Technologies. Gregg is
also a co-developer and
patent holder of the LANAP
laser periodontitis treatment.
He maintains a private practice
where he sees patients. He is
president and chairman of the
board of Millennium Dental
Technologies and president of the
Institute for Advanced Laser
Dentistry. He can be contacted
