Periodontitis therapy with 3,000 percent more power

Author_Darius Moghtader, DDS

_Sometimes by asking questions that nobody has ever asked_ before you break new ground. In my case, this was: how can I help periodontitis patients even more effectively? And the simple answer is: with the “3,000 percent more power” therapy.

What’s that? Is that dangerous? How is that supposed to work? Why do we need this? What’s that supposed to mean?

No one had asked me these questions when I presented the concept (developed in our office in 2007) as a pilot project at IDS. Nevertheless, I shall answer these previously unasked questions here.

_The idea_

I came upon the idea of a different way to treat periodontitis while researching literature on the topic of lasers. The 2003 Yukna Report described the LANAP method. This laser-assisted new attachment procedure promised regeneration instead of repair, combined with a spectacular design. Dr. Yukna of New Orleans had three female patients, each of whom agreed to undergo the study on two single-rooted teeth with plaque. One tooth in each patient was treated using the LANAP method and the other with the Nd:YAG laser in accordance with a standard protocol.

And here’s the kicker (this would happen only in the United States): after monthly recalls, both teeth were removed from the bone block in all three patients!

The histological results showed regenerated bone and new periodontal ligament in two of the three LANAP teeth. The control group had only one long functional epithelium. Neither the root surface nor the pulp showed histological changes.
DOUBLE THE DEAL
SAVE BIG THIS SUMMER ON PICASSO™ LASER TECHNOLOGY

TWO PICASSO LITES FOR ONLY $4,495!

Endorsed by luminaries around the world, AMD LASERS offers innovative technology, world-class solutions, dedicated support, and customer service. For a limited time, get two of our award-winning Picasso Lites for only $4,495!

This Double Deal won’t last long. Contact us today and find out more about how you can take advantage of this double of a deal.

So far so good — anyone who knows me knows that, as a general dentist, I am a fan of the diode laser. The only Nd:YAG laser that can handle the LANAP procedure and is patented for the job is the Millennium Laser from the undisputed master inventor and laser pioneer, Dr. Robert H. Gregg.

**The method**

I analyzed which factors were different from a standard laser protocol and tried to adapt the diode-laser procedure accordingly. Thanks to the support of elexxion, I was able to develop a protocol for the claros at 30W and 20,000Hz.

What clinical indication of successful treatment can we expect based on the Yukna Report? Such an indication is bleeding from the treated socket. As a laser user, I am sure you know that treated sockets can become very dry after normal laser treatment. Many manufacturers even use this as a selling point, and the patient is satisfied as well — after all, there is no more bleeding. The problem is, no blood means no regeneration, no healing, no new bone. Every dentist is familiar with the problems caused by dry sockets. Schulte addressed this concept in the filling of cysts with autologous blood.

**The questions**

*How do we achieve this?*
We achieve this with extremely short impulses at very high wattage levels.

*Is this safe for the patient?*
In order to answer this question, we asked Dr. I. Krejci of the University of Geneva to conduct a pilot study in 2007. The results of the study can be summarized as follows.

At the recommended tested settings, a temperature reduction of up to 20 percent occurred compared with treatment with a 1.11W continuous wave. There were no significant electron microscopical changes to the root. At these settings, no carbonization of the root surfaces took place. Of course, further studies are necessary and desirable to corroborate these results.

*Why do we need this?*
The goal is greater regeneration instead of repair.

*How does this work?*
This works using elap-p, a procedure developed in the dentist’s office for the dentist’s office.
What is elap-p?
Simply put, elap-p means the following: 3,000 percent more power with up to 20 percent less heat generation with no carbonization or coagulation.

Every dentist has experienced first-hand the scenario below.

Case study

Initial scenario
The patient comes into the office on Friday evening with sharp shooting pains and was not able to sleep the night before. Pain medication works only for a short period. Redness and bleeding clearly indicate an acute periodontal cause.

Opening the socket
After local anesthesia, a traditional cleaning, including plaque removal, is first performed, either with an Er:YAG laser or, as shown here, through an ultrasonic periodontal probe. Of course, manual instruments can also be used if preferred. This allows the laser fiber easy access to the site of the inflammation.

Elap-p, the first time around
Laser decontamination is performed using the 810nm, 30W, 5,000Hz diode laser at a pulse duration of 10µs. The average measured output from the 400µm fibre tip is 1.2W. The surface of each tooth is treated using the periodontal handpiece in a grid pattern for five seconds, about 20 seconds per tooth. With a knock-on effect (repeated laser decontamination) on bacteria and intentional forced bleeding with no carbonization or coagulation, the effect of the 30W pulse on the tissue shows an excellent healing prognosis and minimal damage to the gingival tissue, as the blood contains everything for tissue regeneration or repair.

Plaque and toxin removal
The Er:YAG laser, ultrasonic periodontal probe or manual instruments are once again used to remove bacterial debris, toxins (antigens) and plaque.

Elap-p, the second time around
Laser decontamination is repeated using the 810nm, 30W, 5,000Hz diode laser at a pulse duration of 10 µs with an average output from the 400µm fibre tip of 1.2 W. The surface of each tooth is treated using the periodontal handpiece in a grid pattern for five seconds, about 20 seconds per tooth. With a knock-on effect (repeated laser decontamination) on bacteria and intentional forced bleeding with no carbonization or coagulation, the effect of the 30W pulse on the tissue shows an excellent healing prognosis and minimal damage to the gingival tissue, as the blood contains everything for tissue regeneration or repair.

Wound closure
The socket is closed through bidigital pressing of the gingiva.

Soft-laser treatment
Soft-laser treatment is then performed at 75MW, 8,000Hz and 9µs for two minutes to alleviate pain and accelerate wound healing.

Follow-up after 48 hours
The patient comes in on Monday at 8:30 a.m. and reports immediate pain relief directly after treatment. She was able to enjoy the weekend without pain medication or antibiotics and was able to eat anything she wanted later in the evening following treatment.

Comparison between treated side and untreated side
For mobility grades higher than 1, simple acid-etch composite splinting is required. Premature contact leading to non-physiological stress must generally be removed. Naturally, after successful acute treatment, systematic periodontal treatment is to be performed.

Wishing you successful tooth maintenance!
