Cleaning is key

By Aws Alani, UK

Completely disinfecting the canal system is challenging when all factors are considered. If we are looking at the nano level there are approximately 76,000 dentinal tubules per square millimetre of dentine. Each of which can harbour a colony of bacteria. Then there may be inaccessible anatomy such as lateral canals, apical deltas or fins.

It seems that irrigation and instrumentation are both highly inter-related in canal disinfection. Take washing your car for instance, purely covering it with soapy water and rinsing won’t remove the motorway bugs and bird produced projectiles. A good scrubbing with a sponge is needed or if you are really serious about cleaning, a pressure washer! This begs a further question—how would your patients feel if they knew that, more or less, the same or very similar liquid they use to clean their bathroom suites is the same that we use to clean the inside of their teeth? On recent evidence of a dentist to the “stars” appearance on national TV not much—he added that we use to clean the inside of their teeth! On recent evidence of a dentist to the “stars” appearance on national TV not much—he added that we use to clean the inside of their teeth!

Bacteria and the biofilms

Unlike what we once thought, bacteria do not tend to just sit alone and remote from each other. If only they were this antisocial! Bacteria join forces and create a biofilm (a signifi cant decrease in endodontic success. This results in shear stresses in the bulk movement of fiuid when pressure waves are projected, resulting in vortex motion around a fast moving oscillating instrument. This results in shear stresses to tear the biofilm apart.

Energising the irrigant

This can take many forms. The simplest is a straightforward approach of improving the fiuid and displacement into the recesses where airlocks may reside. This can be achieved through applying a GIC point into the prepared canal to displace and disperse.

Ultrasonic irrigation transmits energy by an oscillating instrument. This results in the bulk movement of fiuid when pressure waves are projected, resulting in vortex motion around a fast moving oscillating instrument. This results in shear stresses to tear the biofilm apart.

Keeping the canal clean

Once irrigated and prepared, the clinician has a choice—to obturate or to dress. Some may argue that the canal is cleaned at the end of instrumentation and that for convenience, obturating in a one visit arrangement is the best option. As we know, not all bacteria are removed or killed during treatment. Dressing the canal with calcium hydroxide may continue the...
process of eradication of the residual microorganisms over a 2-week period. The choice between the two schemes sometimes boils down to the presenting factors of the case. Where a tooth is difficult to instrument, has a large lesion or is quite obviously chronically infected with a history of pain, then a for-

ternal body reaction could also develop.

The goal of obturation is to seal the canal system to prevent any reinfection and entomb any bacteria not eradicated by chemomechanical debridement. If the obturation is through the apex, this can have significant implications. GP through the apex can carry bacteria outwith of the canal and exacerbate symptoms. A foreign body reaction could also develop.

We also have to remember that a beautiful obturation of a canal achieved without rubber dam and utilising saline or local anaesthetic irrigation is sub-standard treat-

ment. It can be difficult to assess the “quality” of treatment when a radiograph of a “failed” tooth is ex-
amined in this context. Indeed, an obturation that is short of the radiographic apex having been treated under rubber dam and with copious amounts of irrigation is more likely to be successful than the previous scenario. Attributing too much significance to the radiographic appearance of the obtura-
tion is short-sighted. Indeed, Katezbadeh and colleagues in the late ‘90s witnessed healing in the absence of obturation where teeth were instrumented and irrigated optimally under isolation. Sealants are also antibacterial and aide filling the voids between the GP and the canal system. One further option would be to pro-
vide a sub-seal to each of the canal orifices. This can be achieved by re-

toval of 1 mm of GP and packing a good thick mix of IRM packed with a plugger.

Covering the cusps

The provision of a coronal res-

toration (if provided optimally) can improve the coronal seal while also structurally protecting the underlying tooth tissue. Due to endo-
donotic treatment, resulting in reduction of tissue bulk and stiff-

ness the risk of fracture increases. Where both mesial and distal mar-
gins have not been breached and the access cavity is confined to the occlusal surface, a crown restora-
tion may not be required. Once a margin is breached the tooth is more likely to flex and result in cracks or fractures. A commonly asked question “When should the crown be provided?” Soon after the root canal treatment or when the treatment has proven to be suc-

cessful? If the success of endodon-
tic treatment is significantly in doubt then this should be commu-
nicated to the patient and a well compacted direct restoration may be the best option, otherwise an onlay or if tooth tissue is signifi-
cantly reduced, a crown should be provided soon after completion.

Conclusion

Bacteria are public enemy number one in dentistry. Disin-
festing the root canal system by ir-

rigating in combination with me-

chanical instrumentation is key to success in root canal therapy. Pre-

venting further re-infection or persistence of residual bacteria af-

ter the formal stages of treatment through dressing initially and a quality coronal seal subsequently is as important as the root canal therapy.

Editorial note: Aws Alani is leading a two-year postgraduate diploma in operative dentistry at King’s Col-

lege London Dental Institute.

ROOTS SUMMIT is coming to BERLIN

28 June – 1 July 2018
Berlin, Germany
www.ROOTS-SUMMIT.com
The patient reported on in this article is a student in dentistry and his parents are both dentists. They referred their son to a good endodontist, who then referred the case to me. As always, peers are more than welcome in either of my practices, in Rome and London, so when I treated this case, I had three dentists watching me, a future dentist on the chair, placing a great deal of pressure on me.

The 22-year-old male patient had a history of trauma to his maxillary incisors and arrived at my practice with symptoms related to tooth #21. The tooth, opened in an emergency by the patient’s mother, was tender when prodded, with a moderate level of sensitivity on the respective buccal gingiva. Sensitivity tests were negative for the other central incisor (tooth #12 was positive), and a periapical radiograph showed radiolucency in the periapical areas of both of the central incisors. The apices of these teeth were quite wide and the length of teeth appeared to exceed 25 mm.

My treatment plan was as follows: root canal therapy with two apical plugs with a calcium silicate-based bioactive cement. The patient provided his consent for the treatment of the affected tooth and asked to have the other treated in a subsequent visit.

After isolating with a rubber dam, I removed the temporary filling, and then the entire pulp chamber roof with a low-speed round drill. The working length was immediately evaluated using an electronic apex locator and a 31 mm K-type file. The working length was determined to be 28 mm.

As can be seen in the photographs, the canal was actually quite wide, so I decided to only use an irrigating solution and not a shaping instrument. Root canals are usually shaped so that there will be enough space for proper irrigation and a proper shape for obturation. This usually means giving these canals a tapered shape to ensure good control when obturating. With open apices, a conical shape is not needed, and often there is enough space for placing the irrigating solution deep and close to the apex.

I decided to use only some syringes containing 5 per cent sodium hypochlorite and EDDY, a sonic tip produced by VDW, for delivery of the cleaning solution and to promote turbulence in the endodontic space and shear stress on the canal walls in order to remove the necrotic tissue faster and more effectively. After a rinse with sodium hypochlorite, the sonic tip was moved to and from the working length of the canal for 30 seconds. This procedure was repeated until the sodium hypochlorite seemed to become ineffective, was clear and had no bubbles. I did not use EDTA, as no debris or smear layer was produced.

I suctioned the sodium hypochlorite, checked the working length with a paper point and then obturated the canal with a 3 mm thickness plug of bioactive cement. I then took a radiograph before obturating the rest of the canal with warm gutta-percha. I used a compomer as a temporary filling material.

The symptoms resolved, so I conducted the second treatment only after some months, when the tooth #11 became tender. Tooth #21 had healed. I performed the same procedure and obtained the same outcome (the four-month follow-up radiograph showed healing).

“The immense variability of human tooth anatomy”

An interview with Dr Craig Barrington about his technique for capturing high-definition endodontic images

With his high-definition photography of complex root canal systems, Dr Craig Barrington, who practices dentistry in Waxahachie, Texas, is developing quite a name for himself. Just check out his presence on Facebook, at craigbarringtondds.

In an interview with DT America, Barrington talks about how he captures these high-definition endodontic images and how he uses them to increase his knowledge and help improve the level of care he provides to his patients.

Please tell our readers a little bit about yourself and your dental practice.

Dr Craig Barrington

I graduated Summa Cum Laude from the University of Texas Health Science Center in San Antonio in 1996. I am a general dentist in Waxahachie, Texas, and have been in my current location for 20 years.

What do you like best about practicing dentistry?

I most enjoy the science, the biology and having a front-row seat in and around the ability to interact with, affect and watch the human body function and heal. I appreciate the ability to solve problems and the ability to work on problems that are yet to be solved.

Today, I see characteristics of the internal anatomy of human teeth that I never thought possible or even existed. Visualising the immense variability of human tooth anatomy has changed my clinical practices and improved my clinical results, which benefits the patients I treat.

Do you perform endodontic therapy yourself or do you typically refer cases out?

I do all of my own endodontic treatments in my office. It has taken me years to identify the area of dentistry that I love. Perhaps one day I will take the necessary steps to specialise, but life is currently focused on my family and my children.

Is there anything you would like to add?

I am respectfully honored by this opportunity, your questions and in you finding significance in this work of mine.

The photography is actually not difficult. It is oil immersion oblique illumination light microscopy, which has been done in histology labs for years. It is, however, a new realisation in this area for dentistry. In dentistry, we are familiar with the study of microscopic histologic sections. Teeth, on the other hand, are gross histologic specimens that can understandably be seen via the naked eye; however, viewing of the internal anatomic structures is greatly enhanced with microscopic evaluation. Any photographs of the teeth I work with are simply obtained through my “artist’s eye” or in what I would consider an aesthetically pleasing position.

The photography requires some practice, but one day I will take the necessary steps to specialise, but life is currently focused on my family and my children.

ENDO TRENDS
ROOTS SUMMIT: Registration open for 2018 edition

By DTI

BERLIN, Germany: Seats for the next ROOTS SUMMIT, the premier global discussion forum dedicated to endodontic dentistry, are still available. The event, featuring lectures and workshops, will be held at the European School of Management and Technology (ESMT) in Berlin from 28 June to 1 July 2018. Approximately 500 visitors are expected at the international meeting, which is again being organised in collaboration with Dental Tribune International.

Although the 2018 ROOTS SUMMIT will mainly feature presentations on the latest techniques and technologies in endodontics, the organisers are inviting dental professionals in all fields, as well as manufacturers in the industry, suppliers of endodontic products and anyone involved in the practice of endodontic treatment, to attend.

It has been announced that foremost opinion leaders, including Drs Steve Buchanan, Frederic Barnett, Gergely Benyécs and Elisabetta Cotti, will be speaking at the conference next year. There will also be the opportunity to participate in hands-on workshops, speak to industry professionals on-site and engage with new equipment, procedures and protocols in endodontic dentistry. A number of dental companies specialising in endodontics, including META BIOMED and FKG Dentaire, have already confirmed their participation.

The ROOTS SUMMIT, which started as a mailing list of a large group of endodontic enthusiasts in the 1990s, has grown significantly over the last few years. With currently more than 24,000 members from over 100 countries, it evolved into one of the most prominent global learning forums in the dental industry.

Previous conferences have been held in Canada, the US, Mexico, Spain, the Netherlands, Brazil and India. The 2016 ROOTS SUMMIT took place in the UAE and was one of the most significant events in endodontics that year, drawing over 300 dental professionals to Dubai. These meetings have been known for their strong scientific programmes. An early bird discount of 20 per cent is being offered and dental students too will be granted a 20 per cent discount. Additional information and online registration can be found at www.roots-summit.com.
