Lasers provide an exciting new technology that allows the dentist the ability to give patients optimal care without many of the “four factors” found in conventional dental techniques. Used with proper understanding of laser physics, lasers are extremely safe and effective. Using lasers for caries removal, periodontal treatment, endodontic treatment, bone management, cutting and shaping, and soft-tissue procedures can reduce postoperative discomfort and infection, and provide safe, simple in-office treatment. As a result, we can improve our efficiency, expand what we can do, achieve better results and increase production.

Lasers represent a real quantum leap forward in the treatment of our patients, including the pediatric patient. The U.S. Food and Drug Administration (FDA) gave approval for the use of the Er:YAG laser in 1997 for both hard- and soft-tissue procedures. The endodontic filling material (placed within the YAG crystal) crystal of Yttrium-Aluminum-Garnet’s (Er:YAG) development and success can be made the treatment of children safer and quicker.

Plainly stated, a laser is a piece of equipment that creates a concentrated monochromatic beam of visible or infrared light that can be absorbed by a specific target. Since then, laser-assisted dental care has changed forever the way dentists can prepare diseased teeth, ablate bone and treat soft-tissue abnormalities and disease. An entire new standard of care has been created.

Lasers and laser dentistry are a perfect fit. There are a wide range of hard and soft dental procedures that may be completed using lasers as an alternative to conventional dental care on adults and, especially, children. Many of these procedures may be treatments dentists historically refer to other specialists; however, if you understand and use your laser efficiently, you will discover that many of these procedures that every dentist can complete.

The question that is often the major concern and barrier to implementing lasers in the office is how this innovative technology may be used for procedures that may be completed with a perfect fit. There are a wide range of hard and soft dental procedures that may be completed using lasers as an alternative to conventional dental care on adults and, especially, children. Many of these procedures may be treatments dentists historically refer to other specialists; however, if you understand and use your laser efficiently, you will discover that many of these procedures that every dentist can complete.

Lasers represent a fundamental change in the entire way dentistry has been taught. We can now rethink and often modify G.V. Black’s principle of prevention for the concept of minimally invasive dental treatment. We need to understand that laser dentistry is one portion of an entire new way of practicing conservative, pain-free dentistry.

The laser that we call the “all-purpose” laser is the Lightwalker Er:YAG and Nd:YAG laser, manufactured by Fotona and distributed in the United States by Technology 4Medicine. The Er:YAG produces its effect at 2940 nm and has as its primary absorption water and hydroxyapatite. It is very safe, relatively quiet, eliminates the smells and vibrations associated with the dental handpiece and, most importantly, is much more comfortable for the patient, significantly reducing the need for local anesthesia.

The use of the new generation erbium lasers for repair of incipient hard tissue disease allows the dentist to provide a stress-free means of restoring teeth in a minimally invasive manner, most often with no shot and no numb lip, without the need for any local anesthetics.

The erbium laser can be used for restorative primary and permanent teeth, eliminating or reducing the amount of local anesthetics. In most cases, the patient will not require numbing for Class 1, 2 (sometimes), 3, 4, 5, 6 restorative procedures using bonded restorative materials. Using the concept of minimally invasive restorative procedures, the Er:YAG laser allows the operator to remove only diseased tissue and thus preserves much more of the health, unaffected tooth.

In cases where alloy is preferred, the laser’s analysis effect may also allow the dentist to create a restorative preparation using a conventional handpiece that is not meant for bonding. The erbium laser is effective because of its effect on its target, water, within the tooth structure. This effect occurs when the laser heats up water within the target tissue, causing it to create small microscopic explosions (photothermal effect) when it is applied to soft tissue, bone or teeth and cavities, the explosions then cause the areas to be vaporized.

Er:YAG laser 2940 nm: Soft-tissue procedures

There is a wide array of soft-tissue procedures that can be completed using the all-purpose laser: maxillary and mandibular frenum resections, lingual frenum resections, treatment of pericoronal pain or infection, removal of hyperplastic tissue, removal of oral cavity in orthodontic patients, biopsies, treatment of aphthous ulcers and herpes labialis, pulpotomies, removal of impacted teeth and, in adults, apicectomies and bone contouring.

Pulpotomies

Parents often express concern about the need to take radiographs because of the nature of X-rays and their possible side effects on a child’s overall health. They question the use of alloys because of the chemical makeup of the alloy. Whether these should be a real concern in today’s dental care is open to debate, depending on your individual beliefs. There are also concerns by many, although not as loudly, about the effect of various pulpotomy procedures used in pulpotomy procedures, such as silverpoints. Lasers provide a safe, non-chemiccal, effective, and alternative treatment for pulpotomies. During the span of eight years, post-treatment results on more than 4,000 pulpotomies using the erbium (2940 nm) laser provide ample evidence that this method is both effective and safe for children without the need for introducing chemicals or using electron-surgery methods.

When the final result of orthodontic positioning of the front teeth results in gingival hypertrophy, the laser can be a useful tool in increase crown length and give the patient a more esthetic smile. This may be accomplished with the use of additional procedures that can be completed with the erbium. In addition to the many examples described in this article, lasers can be used in additional procedures not usually required in pediatric dentistry, such as revisions of the abnormal mandibular frenum, often avoiding the need for soft-tissue grafts, crown-lengthening procedures where bone recontouring, apicoectomies, removal of bone exostoses, removal of third molar impactions, removal of root remnants, incising and shaving soft-tissue infections, advanced periodontal treatments and the latest in advanced endodontic treatment via photoinduced photoacoustic streaming.

Photoacoustic endodontics using PIPS

The goal of endodontic treatment is to obtain effective cleaning and decontamination of the smear layer, bacteria and their byproducts in the root canal system. Clinically, traditional endodontic techniques use mechanichcal instruments, as well as ultrasonic and chemical irrigation, in an attempt to shape, clean and completely decontaminate the endodontic system but still fail short of successfully removing all of the infective microorganisms and debris. This is because of the complex root canal anatomy and the inability for common irrigants to penetrate into the lateral canals and the apical ramifications. It seems, therefore, appropriate to search for new materials, techniques and technologies that can improve the cleaning and the decontamination of these anatomical areas.

Among the new technologies, the laser has been studied in endodontics since the early 1970s and has become more widely used since the 90s. Different wavelengths have been shown to be effective in significantly reducing the bacteria in the infected canals, and important studies have confirmed these results in vitro. Studies reported that near infrared laser are highly efficient in disinfecting the root canal surfaces and the dentinal walls (up to 75% killing the diode 810 nm and up to 4 mil for the Nd:YAG 1064 nm). On the other hand, these wavelengths did not show effective results in debridging and cleaning the root canal surfaces and caused characteristic morphological alterations of the dentinal wall. The smearlayer was only partially removed and the dentinal tubules primarily closed as a result of melting of the inorganic dentinal structures. Other studies reported the ability of the medium infrared laser in debriding and cleaning root canal walls. The bacterial load reduction after erbium laser irradiation demonstrated high on the dentin surfaces but low in depth of penetration because of the high absorption of laser energy on the dentin surface. Also the laser activation of commonly used tricalcium phosphate (TCP) resulted in statistically more effective removal of debris and smear layer in root canals compared with traditional techniques (U3) and ultrasound (PU). Additionally, the laser activation method resulted in a strong modulation in reaction rate and CAPP designates this activity for 2 CE credits.
of NaOCl significantly increasing production and consumption of available chlorine in comparison to ultrasound activation. A recent study has reported how the use of an Er:YAG laser, equipped with a newly designed radial and striped tip, in combination with 17 percent EDTA solution, results in very high pulpal closure (50 microsecond) and low energy (20 ml) resulted in effective debris and smear layer removal with minimal or no thermal damage to the organic dental structure through a photoacoustic technique called photon induced photoacoustic streaming or “PIPS.” Also, the same photoacoustic protocol in combination with 5.25 percent sodium hypochlorite (NaOCl) has been investigated and shown to reduce the bacterial load and its associated biofilm in the root canal system three dimensionally. Other similar studies are in progress for publication and the results are promising and suggest a three-dimensional positive effect of this laser-activated decontamination (LAD) method.

**Scientific background**

The microphotographic recording of the laser second, used in dry mode, of the LAD studies suggested that the erbium lasers used in irrigant- filled root canals generate a streaming of fluids at high speed through a cavitation effect. The laser thermal effect generates the expansion implosion of the water molecules of the irrigant solution, generating a secondary cavitation effect on the intracanal fluids. To accomplish this streaming, it is suggested the fiber be placed in the middle-third of the canal, 5 mm from the apex and stationary. This concept greatly simplifies the laser technique, without the need to reach the apex and to negotiate radicular curves. Also, the recorded video of the new technique, PIPS, showed a strong agitation of the liquids inside the canals. It differs from the already cited LAD technique by activating the irrigant solutions in microporous cavitation rather than a profound photoacoustic and photomechanical phenomena. The use of low energy (50 microsecond pulse, 20 ml at 15 Hz, 0.5 W average power, or less) generates only a minimal thermal effect. The study with thermocouples applied to the radicular apical third revealed only 1.2 degrees C of thermal rise after 20 seconds and 1.5 degrees C after 40 seconds of continuous radiation. When the erbium laser energy is delivered at only 50 microsecond pulse duration through a special designed tapered and stripped 400 microns tip (Fotonla Light-Walker, Technology4Medicine), it produces a large peak power of 400-watts when compared to a longer pulse duration. Each impulse, absorbed by the water molecules, creates a microexplosion or “wave” that leads to the formation of an effective streaming of fluids inside the canal while also limiting the undesirable thermal effects seen with other methodologies. The placement of the tip in the coronal portion only of the treated tooth allows for a more minimally enlarged canal preparation with less thermal damage as seen with those techniques placed into the canal system. The root canal surfaces irrigated with 17 percent EDTA and laser activated for 20 seconds showed exposed collagen matrix, opened tubules and the absence of smear layer and debris (Figs. 1-5). The running with 5.25 percent sodium hypochlorite and laser irradiation for 20 seconds produced a strong activation of the solution, as reported by Macesic, improving the disinfecting action of the sodium hypochlorite. The disinfecting action of PIPS is very effective both on the root surface, the lateral canals and the dentinal tubules, as confirmed with SEM and confocal studies (Fig. 4). The profound and distant effect of PIPS eliminates the need to introduce the tip into the root canal system. Unlike traditional laser techniques requiring placement of the tip 1 mm from the apex, or even 5 mm from the apex as proposed for LAD, the PIPS tip is placed in the coronal portion of the pulpal chamber only and left stationary, allowing the photoacoustic effect to spread into the opening of each canal. A new tip design consisting of a 400-micron diameter, 12 mm long tapered end is used for this technique (Fig. 3). The final 5 mm of coating is stripped from the end to allow for greater lateral emission of energy compared to the frontal tip. This mode of energy emission allows for improved lateral diffusion with low energy and enhanced photoacoustic effect.

**Discussion**

Laser irradiation is a common technique used in endodontics to improve the cleaning, the debridging and disinfection of the root canal system. Many wave-lengths and protocols are used. Near infrared lasers are used for the three-dimensional decontamination of the endodontic system. Nd:YAG and diode lasers use thermal energy to destroy bacteria. Observations reveal a certain grade of thermal injury to the root canal surface and creates a typical morphological damage. Moreover, they are not able to thoroughly remove the smear layer. On the contrary, erbium lasers are used for their effective smear layer removal while their bactericidal activity is limited to the root surface. The placing of the tip close to the apex and its back movement during the activation process is related to the risk of apical perforation, ledgeing and surface thermal damage, because of the ablation ability of this wave-length. Also a combination of the near and medium infrared lasers has been proposed. A technique, called twillight endodontic treatment (TET), uses the erbium laser energy first, to clean the root canal surface and remove the smear layer and the Neodinium:YAG laser second, used in dry mode as the final disinfecting step. All these techniques utilize traditional tips and fibers placed into the canal, close to the apex (1 mm) with all the corresponding thermal disadvantages observed in long, narrow and curve canals. The erbium lasers are also used as a medium of activation of commonly used irrigants (LAs), avoiding the risk of thermal damage, while increasing the cleaning and disinfecting activity of the fluids. PIPS, in particular, reduces all these risks and disadvantages, thanks to the position of the tip in the coronal orifice only and to the use of minimally ablative energy levels of 20 mJ or less.

The findings of our studies demonstrated that PIPS technique resulted in a safe and effective debridging and decontaminating of the root canal system. Our clinical trials showed that PIPS technique greatly simplifies root canal therapy while facilitating the search for the apical terminus, debridging and maintaining patency. As a result of the efficacy of PIPS, the final size required for canal shaping can be significantly reduced, offered to a size 25/04, allowing for a more minimally invasive and biomimetic preparation that can then be obturated three dimensionally.

**Conclusion**

Lasers are an extremely versatile addition to the dental practice and can be used in many instances instead of the conventional methods employed by the vast majority of dentists. Incorporating a laser in the dental practice should be viewed as an investment rather than a cost. When used with a good knowledge of laser physics, training and safety, lasers provide our patients a new standard of dental care.
