Always a perfect healing with P.R.F. (platelet-rich fibrin)

By Dr. Dominique Caron

After any weird wisdom tooth extraction here is a first quick introduction to a smart technique.

You are happy, your bony complication, looking like a plug for hollow brick, is out.

The process

Just before starting the surgery, a nurse draws blood from the patient into plain tubes, about 10 ml.

The clotting cascade starts immediately so try to be quick with the blood collection and immediate centrifugation: around 2800 rpm 10 mm.

What does it change?

- Hemostasis: You get a quick clot filling the socket (that allows much less food collection)
- The dental nerve is immediately protected
- Accelerated tissue remodeling:
  - Fast neovascularization.
  - Even lower risk of infection.
  - Pain is reduced.
  - Inflammation is lower during the following days.
- EFFICIENT: Enhances the body’s natural healing.
- SAFE: No biochemical handling, strictly autologous.
- EFFICIENT: Enhances the body’s natural healing.

To conclude, this smart French technique can render your patient’s life and yours much happier!

Stay tuned for further articles with all other applications.
