‘Oral tissue contains a kind of powerful stem cell’

Tissue engineering is based on the concept that the human body, or parts of it, can be regenerated using stem cells. Since the 1980s, several types of tissue and organs have been generated worldwide using cultured living cells.

Dental Tribune Asia Pacific, in cooperation with FDI’s Worldental Daily, spoke with Dr. Minoru Ueda from Nagoya University in Japan about key tissue-engineering strategies and their potential for dentistry.

Dr. Ueda, tissue engineering is a relatively new approach in regenerative medicine. How did it find its way into dentistry?

The basic concepts and strategies for tissue regeneration are general. To regenerate any tissue, we need stem cells, growth factors and a scaffold.

In the field of dentistry, we have made much scientific progress in terms of materials, which gives us an advantage over other fields of medicine. We began with developing high-quality materials and then expanded to using stem cells.

What are the key tissue-engineering strategies that are currently being developed for dentistry and how do they work?

The most important tissue for dentistry is bone. We are establishing technologies for bone tissue engineering and apply these clinically to implant surgery. Secondly, we are focusing on stem cell science.

Oral tissue contains a kind of powerful stem cell that can be used to treat systemic diseases, such as brain infarction or heart infarction. The dental pulp stem cell is one of the most important cells derived from oral tissue.

‘You’ve taken implant training; what do you do next?’

By Lynn Mortilla, RDH

Integrating implants into a practice is a job for the whole team as much as it is for the dentist. It is critically important to focus on the “other” skills necessary after clinical competencies are learned. A necessary step is to be sure not only the clinician but the entire team is trained for implant dentistry. Everyone in the practice plays an integral role for successful incorporation of systems, strategies and techniques to enhance the success of implant dentistry. These techniques should be built into daily protocols. Standardized forms and tools can also aid the implant-focused practice.
Is it possible to reconstruct complex tissue defects made up of multiple cell types? Yes, it is. We have succeeded in reconstructing the structures that make up periodontal tissues, which are cementum, bone and periodontal ligament in humans.

There is different legislation around the world regarding stem cell research. Would you please explain how the situation in Japan differs from other parts of the world and its effect on your research?

We can do basic research using animal cells and human stem cells, but research using embryonic stem cells [ES] and induced pluripotent stem cells [iPS] must be performed under the control of the ethical committees of each university.

In order to use ES or iPS, we need special permission from our university and government. Clinical studies based on basic research also require approval from our university and government.

It is actually very difficult to gain approval compared to other countries. So it is easy to conduct basic research, but very difficult to conduct clinical studies in Japan.

Current debate in the field of cosmetic dentistry centers on whether dentists should be allowed to inject osteogenic cells into patients for non-dental reasons. What is your opinion on this matter? Dentists should not be allowed to inject any cells by themselves for non-dental reasons.

However, for cosmetic reasons, dentists can inject stem cells into the oral and maxillofacial areas, especially into the face because cosmetic problems such as wrinkles are not a disease.

The surface structures of an implant are very important, but this is not a main factor for enhancing the living cell around the fixture.

What effect will tissue engineering have on dental practice during the next 20 to 25 years? Tissue engineering could provide a new treatment method for diseases that have not been treatable thus far, such as severe periodontitis and atrophied alveolar ridges.

Also, cosmetic therapy using tissue engineering in the oral and maxillofacial regions will become commonplace in the dental practice.

(Tissue engineering could provide a new treatment method for diseases that have not been treatable thus far, as shown by research that was starting to become commonplace in the dental practice. This interview is published with permission by the FDI World Dental Federation.)
