Caries removal and esthetic direct composite restorations

By Ian Shuman, DDS, MAGD

When treating a carious lesion, it is critical to identify and remove only infected tooth structure, avoiding the needless removal of healthy tissue. Past techniques were unreliable for the sole removal of diseased tissue; however, current advances have improved both the recognition of what is considered active caries and those methods for its elimination.

Research conducted at Temple University has verified that a new instrument made from a unique polymer resin technology is able to remove decay, and unlike caribides and other burs, is the only rotary cutting instrument that is incapable of cutting healthy tissue. The Smartburs II works because it is harder than decay, but not as hard as healthy dentin.

Mode of operation

The Smartburs II uses an extraordinary concept in blade configuration and material structure, allowing it to remove carious dentin only, and rendering it incapable of cutting healthy dentinal tissue. By eliminating contact with the dentinal tubules, pain is virtually eliminated. During the removal process, patients have reported only a feeling of pressure, thereby eliminating the need for anesthesia.

This improvement in clinical efficiency translates into savings of both time and cost and an increase in patient referrals. In cases where the lesion is deep and anesthesia is required, pulp exposure can be greatly reduced, providing safer, more comfortable and effective treatment; making it is critical to identify and remove only infected tooth structure, avoiding the needless removal of healthy tissue.

The accreditation process, which was developed by the AACD and is the world’s most recognized advanced credentialing program, encourages further education, inter-action with like-minded colleagues and the opportunity for professional growth. Accreditation requires dedication to continuing education and responsible patient care. “We are honored to welcome these professionals to the ranks of AACD accredited members,” said Dr. Nils Olson, chairperson for AACD Accreditation. “Accredited dentists and laboratory technicians are the most passionate and committed dental professionals. Those who have achieved accreditation have improved their skills, acquired new techniques and can provide their patients with better care and services.”

“They understand that a smile is more than just an anatomical part, it’s an expression of who their patients are,” Olson added.

The newly accredited dental professionals will receive their accreditation and award at a special ceremony during the 27th Annual AACD Scientific Session, to be held May 18–21 in Boston. For more information about AACD accreditation, visit www.AACD.com/accreditation.

About the AACD

The AACD is the world’s largest non-profit member organization dedicated to advancing excellence in comprehensive oral care that combines art and science to optimize improve dental health, esthetics and function.

Composed of more than 6,500 cosmetic dental professionals in 70 countries worldwide, the AACD fulfills its mission by offering superior educational opportunities, promoting and supporting a respected accreditation credential, serving as a user-friendly and inviting forum for the creative exchange of knowledge and ideas, and providing accurate and useful information to the public and the profession.

NEWLY AWARDED AACD ACREDITATION

28 earned AACD accreditation: largest class in history

The American Academy of Cosmetic Dentistry (AACD) announced that 28 dental professionals have recently been awarded accreditation status—the largest group to be awarded the coveted AACD credential to date.

There are only 351 dental professionals worldwide who have achieved this prestigious honor, having reached this achievement after completing a rigorous credentialing process including a written examination, oral examination and the submission of clinical cases for peer-reviewed evaluation.

These professionals practice internationally and in the United States. The newly accredited AACD members are shown in the box at right.

The accreditation process, which was developed by the AACD and is the world’s most recognized advanced credentialing program, encourages further education, interaction with like-minded colleagues and the opportunity for professional growth. patient outcome — especially in deep preparations — more predictable.

Removing decayed dentin with Smartburs II

Step 1: In order to use the Smartburs II properly, an operating range of 5,000–10,000 rpm in a standard slow speed is ideal and increases the longevity of the bur. In addition, a light brushstroke is used during operation, essentially teasing out the carious tissue.

This is a significant departure from previous techniques using traditional carbide and diamond burs.

Step 2: When treating a carious lesion, it is critical that sharp and ragged enamel edges be removed with an appropriate high-speed bur before introducing the Smartburs II to avoid dulling the instrument.

The Smartburs II is then introduced into the center of the lesion.

This helps to avoid unnecessary initial contact with healthy enamel and dentin that could prematurely dull the bur.

Step 3: Starting in the center of the lesion, the most superficial, softest decay is removed using the largest size Smartburs II. The next smaller size Smartburs II is then worked laterally, removing layer by layer throughout the lesion, finally cleaning the entire cavity floor.

The removal of caries to the cavity floor in one area only will prematurely dull the instrument and make caries removal in adjacent areas more difficult.

It is important to emphasize that contact of Smartburs II with hard enamel, healthy dentin or restorative materials will result in dulling and premature failure of Smartburs II.

Step 4: The last action with the Smartburs II is to clean the cavity floor with more forceful strokes. Here you will have increased tactile sense when encountering decay versus using standard carbide burs.

This enables the conservation of healthy tissue when the self-limiting action of the Smartburs II instrument is experienced. After using the Smartburs II instrument, a careful examination of the area is required to confirm complete decay removal.

Case report

A patient reported with the chief complaint of having cavities in his upper front teeth (Fig. 1a). He reported no discomfort, but was self-conscious about his appearance. Upon examination, the maxillary anterior teeth were diagnosed with both Class V and Class III carious lesions.

A treatment plan was formed that would include the restoration of these teeth using a direct composite resin technique with the possibility of root canal therapy where required.

Following the administration of local anesthesia, the cavity preparation for the maxillary right cen-
For many years, people with chronic dental problems or missing teeth had limited options. They could continue with the endless cycle and expense of root canals, crowns and other restorations; live with the chewing, speaking and comfort problems often associated with dentures; or pay the extremely high costs of dental implants. Now Drs. Andrew Spector and Michael Migdal, practitioners in Havorth, N.J., who have long been at the forefront of dental implant technology, are one of a relative handful of dentists throughout the country (and the only ones in the New York metropolitan area) to offer patients the benefits of “permanent teeth” at about half to one-third the cost of implants, and in a fraction of the time.

Hybridge” — a hybrid bridge system — is a mix between a conventional fixed bridge and a denture. Unlike a conventional bridge made of metal and porcelain, the system uses a resin and titanium bridge restoration that replaces up to 12 teeth and is supported on five or six dental implants. It is not intended for people requiring single tooth implants, but rather sectional or complete mouth restoration.

As with conventional implants and unlike dentures, they sit on implants rather than the gum line for greater comfort, allow people to eat and chew as they would with their own teeth, and stimulate the jawbone (thereby preventing the “caved in” look found in people with years of denture wearing).

The teeth look, feel and function just like healthy, natural teeth and last a lifetime. As with conventional implants and unlike dentures, they sit on implants rather than the gum line for greater comfort, allow people to eat and chew as they would with their own teeth, and stimulate the jawbone (thereby preventing the “caved in” look found in people with years of denture wearing).

While a fixed bridge or removable dentures works for cosmetic reasons, and allows the individual to chew as they would with their own teeth, and stimulate the jawbone (thereby preventing the “caved in” look found in people with years of denture wearing), these options are prohibitive for many who require full mouth or arch restoration, as many older people do.”

Patients for the Hybridge system tend to be older, according to the American Association of Oral and Maxillofacial Surgeons, and by age 74 more than one in four American adults have lost all their permanent teeth.

Yet, Spector said that he has also recommended Hybridge for patients who have lost their teeth as a result of early periodontal disease, traumatic injuries and eating disorders, such as bulimia, which cause tooth decay.

Meanwhile, removable dentures can slip, cause embarrassing clicking sounds and lead to bone loss around teeth they are hooked onto. “The efficiency and precision of the fabrication with the Hybridge system allows us to keep the fee far lower than traditional implant treatment for those patients who need to replace an entire upper or lower archway,” said Spector, who has been at the forefront of dental implants for many years and taught implantology at NYU Dental School.

“While dental implants remain the ‘gold standard’ for patients replacing single teeth, the cost makes them

New option for missing teeth

About the author

Dr. Ian Shuman maintains a full-time general, reconstructive and aesthetic dental practice in Pasadena, Md. Shuman is a master in the Academy of General Dentistry, a fellow of the Pierre Fauchard Academy and a member of the ADA and the AAID. Since 2005, he has been voted one of the Top 100 Clinicians in Continuing Dental Education in North America by Dentistry Today and was voted Baltimore’s Top Doc by Baltimore Magazine in 2008 and 2009. He is also the official dentist and a regular guest on Baltimore’s No. 1 morning radio show, “98 Rock.”
