Daniel Zimmermann, recalls a successful meeting in Edinburgh for the European Society of Endodontology

The auditorium filled with the sound of Scottish bagpipes, but not playing the familiar tunes of folk classics such as Amazing Grace or Auld Lang Syne; it was the famous guitar intro from AC/DC’s 1990 track Thunderstruck as re-interpreted by the Red Hot Chilli Pipers. The performance by the Scottish ensemble, who won the BBC’s When Will I Be Famous television show in 2007 and conquering stages in Scotland and worldwide with energetic bagpipe rock, was one of the highlights of this year’s European Society of Endodontology (ESE) congress in Edinburgh.

The 14th biennial ESE meeting, which was the second held in the UK (the first was the London congress in 1993), saw a record attendance of more than 1,400 endodontic specialists from 50 countries. They had been invited to join a comprehensive lecture programme discussing key issues such as the rights and wrongs of different instrumentation as well as the realities of microbial biofilms and the challenges of 3-D imaging.

New this year was a significant offering of 20-minute presentations that illustrated the latest clinical findings from research groups throughout Europe and further afield.

At the accompanying trade show, the company W&H presented its new anaesthetic system Anesto that allows targeted local anaesthetisation of individual.

Delegates at the General Assembly elected former ESE secretary Prof Claus Löst as new president. Prof Löst is currently Clinical Director of the Center of Dentistry, Oral Medicine and Maxillofacial Surgery at the Tübingen University Hospital in Germany. He will succeed incumbent president Prof Gunnar Bergenholtz from Sweden at the beginning of 2010. More staff changes are expected to be announced soon. Amongst others, treasurer Prof Dag Ørstavik from Norway will step down.

The Executive Board proposed the co-funding of a symposium in July 2010 with the Pulp Biology and Regeneration Group of the International Association for Dental Research, which will address the topics of inflammation and regeneration.

ESE, founded in April 1982, is a federal organisation representing national endodontic and dental societies in 27 European countries. The next congresses will take place in Rome (Italy) in 2011 and in Lisbon (Portugal) in 2013.
S
uccessful crown preparations start at the diagnosis. Early detection of the need for full coverage restoration can minimise many difficulties associated with the preparation of a tooth for a crown, obtaining an accurate impression, and the achievement of a precise fitting, long-lasting, esthetic restoration. Proper diagnosis is the all important first step.

The importance of vision

The second most important ingredient is vision. The dental operating microscope (DOM) has shown itself to be valuable in endodontics, but it is just as valuable or more valuable with restorative efforts. High magnification above 4X is necessary to impose/create good finish lines that are easy to impress and temporise. Magnification of 2X-24X is available with the DOM. Management of gingival health and biologic width is important to the overall final look of the crown and the cleanliness by the patient. A poor finish line and a poorly positioned finish line results not only in poor impressions and final restoration fit but also makes for poor fitting provisionals.

If one cannot find their own finish line, one cannot properly trim and fit the provisional restoration and remove any temporary cement properly. When patients return, gingival tissues can be irritated making the placement of the final restoration challenging. If by chance one does achieve a good fit, then when the soft tissue heals, the junction of the final restoration and the tooth may be visible and the overall esthetics ruined.

Good patient management

Working at high magnification with the DOM requires good patient and procedural management. If the patient is moving or uncomfortable, then the operator cannot focus and concentrate on proper reduction or the task of placing a solid, conservative finish line on the tooth. Therefore, the third most important ingredient in crown prep success is the dental rubber dam.

For most, using a dental dam for a crown prep is a widely misunderstood concept. Simply put, the rubber dam is the most under-utilised, inexpensive and simple piece of equipment an operator can incorporate into his/her crown preparation protocol. With a little training, dentists and assistants can learn techniques that will benefit all individuals involved in the restoration of a tooth or teeth. Note in all of the photographs that a dental dam is in place before and after.

Tissue management is the fourth concern and this points back to the number one concern of early diagnosis versus waiting until a tooth is severely decayed or broken down. Working deep subgingival and in irritated tissues exponentially complicates the task of crown preparation. Hemorrhagic areas, or those that are deep subgingival, can be difficult to visualise and control. Early diagnosis can minimise these tissue complica-

Of visual importance

Dr Craig Barrington discusses crown preparation techniques utilising the dental operating microscope
Radiosurgery instruments
Lasers have been in dentistry for quite some time but their cost and other fundamental limitations make them difficult to acquire and use. However, radiosurgery has been around for years and is an affordable and useful instrument that can solve many problems regarding finish line visualisation, finish line exposure, and hemorrhage control. In addition, this simple, conservative machine can make cord placement quick and simple by preserving the gingival architecture.

The Parkell unit with a #118 tip allows the creation of a very conservative “trough” or “trench” around a tooth. In combination with good visualisation from the dental operating microscope (DOM), and good patient and procedural management with the rubber dam, we can reliably create a finish line, expose it, place a cord if necessary and impress it.

With a radiosurgical unit, inflamed tissue can be removed such that the healthier tissue is exposed to our hemostatic agents. Healthy hemorrhagic tissue responds better to hemostatic agents than inflamed hemorrhagic tissue. When inflamed tissue are encountered, use of high magnification and the radiosurgical tip to conservatively contour or remove this nuisance tissue can provide predictable result. Removing tissue “thickness” and not modifying tissue “height” can leave the gingival tissue in proper position such that we achieve nice esthetics in our final result.

Handpiece and bur choices
The final item and of least concern in this protocol is handpiece choice and bur choices. There is existing debate between electric versus air driven hand pieces and over which bur is best for which task. The specification of a particular handpiece or bur, would be similar to directing an artist over which paintbrush to use. “What works in one’s hands” is clearly an important factor and that changes from individual to individual and situation to clinical situation. If a practitioner will meet the diagnosis, magnification, isolation and tissue management protocol, then burs and handpiece choices will fall into place on their own with time and experience. I typically use an air driven handpiece and an assortment of Axis turbo diamonds.

In a stepwise fashion for an individual crown prep, the primary concern is achievement of proper anesthesia such that the patient is comfortable in all capacities. Once this is done, the rubber dam is placed. I use a split or “slit” dam technique. The key to success with this rubber dam technique and crown preparations is the distance at which the holes or place apart from each other. Generally speaking, holes are punched too close together for this technique. It is best to punch the holes at a distance from each other on the dam that essentially matches the true anatomical distance between the teeth to be isolated.

Next step: occlusal reduction
Once the tooth is isolated and the patient is confirmed to be comfortable, the next step is the occlusal reduction. This makes the tooth shorter and allows better access and visualisation for the axial reduction. If there is an existing restoration in the form of an alloy or composite filling, it is removed, and the tooth is reduced to the level of the depth of this restoration. Existing restorations usually provide a fine guide to getting nice occlusal clearance without having to verify prior to the next step. Hopefully, I have not diminished the importance of this step as I know this can make or literally break a final restoration.

Doing the occlusal reduction first allows me to get “warmed up” and work out any kinks in terms of patient issues, patient positioning, handpiece water flow or bur choice etc, before moving to the more complicated axial reduction. On the upper arch the full crown preparation is done with a mirror and indirect vision. The microscope puts us in an ergonomic position for doing this and the rubber dam creates a nice situation for a high volume suction to create an air flow that will keep our mirrors clean(er) of the water spray from the handpiece. On the lower arch, I will do ⅔ of the procedure.
with direct vision and then fin-

With direct vision and then fin-

The axial surface reduced first depends on which tooth is being treated. For example, I am right-handed, so on an upper right first molar I reduce the palatal side first and then move to the interproximals. On an upper right first molar I break contact on the mesial first, moving from the palatal side breaking the contact towards the buccal side.

This is the easier of the two surfaces to break. First, it is further forward in the mouth and therefore easier to reach and sec-ond, it is a shorter contact as it is against a premolar. Following the mesial contact break, I con-tinue around the tooth through the mesio-buccal line angle onto the buccal surface. I then break the distal contact, also moving from the palatal side to buccal direction. The most challenging area to prep on an upper right first molar is the disto-buccal line angle. So I prepare the tooth as far as I can through the dis-tal contact and around the disto-

The lower arch is different from the upper arch in that direct vision can be utilised for most of the preparation. The buccal reduction is done first on both lower arches and interproximal contact is broken in a buccal to lingual direction starting with the mesial contact first. Once both mesial and distal contacts have been broken, the lingual reduction is accomplished. For a lower tooth, the disto-lingual line angle tends to be the most difficult area to visualise so this is the part that is refined using indirect vision.

With indirect vision, the difficulty varies depending on the tooth being treated and/or patient, tooth limitations.
Treating a calcified mandibular molar: A Modern Day Protocol

Rafael Michiels, DDS, MSc presents a case study showing old dogs can use new tricks for success

Endodontics has evolved enormously in the last few decades. However, the basic principles from the past are still up to date. This case report gives an example of how the old principles are carried out with newer techniques, devices and materials.

History & Diagnosis
A 37-year-old female patient, was referred to our practice for a problem with the lower right second mandibular molar (4.7). She had no health issues, and was given an ASA score of 1.

The referring dentist opened the tooth, because of an acute pulpitis due to an extensive carious lesion disto-lingually. She had difficulties in locating the mesial canals because the pulp chamber was heavily calcified. She placed calciumhydroxide upon the orifices of the canals and sealed the tooth with a cotton pellet and a temporary restoration, before referring the patient to our office. The patient had no clinical symptoms when she came to our office for treatment.

Treatment & Discussion
A diagnostic radiograph (Fig.1) was taken to see the extent of the lesion and to have a look at the anatomy of the roots. It is essential to determine your strategy. The patient was then anesthetised by giving a lower alveolar nerve block with articaine 4 per cent - 1/100000 epinephrine. (Sep-nerve block with articaïne 4 per cent - 1/100000 epinephrine (Septodent Spécial, Septodent, Belgium) mounted on the Flexostill (Canon Belgium, Diegem, Belgium). Photos were taken with a Canon powershot M50 IS (Canon Belgium, Diegem, Belgium) several times throughout the procedure.

Visualisation and magnification can greatly help clinicians in cases like this one. Without the use of a surgical operating microscope it is very difficult to locate canals when there is much calcification. “You cannot treat, what you cannot see.” is a quote that is regularly heard, but it hits the nail on the head. Visualisation and magnification were obtained through the surgical operating microscope (Opmi Pico, Carl Zeiss Belgium, Zaventem, Belgium). Photos were taken with a Canon powershot SX50 HS (Canalend, Belgium, Diegem, Belgium) mounted on the Flexostill adapter (Carl Zeiss Belgium, Zaventem, Belgium).

“Isolation is one of the fundamental principles in endodontics and is more than 100 years old. Already in 1884 Sanford C. Barber developed the rubber dam.”

By now, a cleaning cavity was created. From here on, I could start with the actual root canal treatment. Two mesial canals were located and coronally pre-flared with Protaper SX (Dentsply Maillefer, Ballaigues, Switzerland). This was also removed with LN burs (Dentsply Maillefer, Ballaigues, Switzerland) and a root ZX mini apex locator (J. Morita Europe, Dietzenbach, Germany). A glide path was then established with K-flexoxles sizes 15 and 20. Cleaning was performed with NaOCl 5 per cent, which was ultrasonically activated with an Irrisafe tip. (Satellite, Mérignac Cedex, France) several times during the procedure. This results in a significant better removal of debris out of the apical part of the root. In order to get a bigger apical diameter, a Profile...
