The beauty of modern materials
Dr Ian Cline discusses how to achieve clinical success with posterior composites

Composite and ceramic tooth-like restorations are without doubt favoured by most patients. These restorations are also, increasingly, the choice of the clinician and a significant number of practices have now become amalgam-free. Posterior composite restorations offer a number of advantages over amalgam, such as excellent aesthetics, minimal preparation of tooth tissue, and the potential reinforcement of tooth tissue. Amalgam has served the dental profession well for more than a century and is a fairly forgiving material in terms of placement and shaping. Composite on the other hand presents a number of difficulties in isolation, dentine bonding and material placement. In particular, when restoring interproximal lesions, technique and operator ability become of the utmost importance. Otherwise, numerous complications may result. These include post-operative sensitivity, premature failure of the restoration due to microleakage and recurrent caries. Of particular difficulty are the production of good contact areas/points and the reproduction of good interproximal form.

Clinical case to illustrate key aspects required for success (Figures 1-6).

When providing a posterior composite, there are several phases. At each phase, things can and do go wrong and each phase requires attention to detail. Of particular importance are:

1. Isolation
2. Tooth preparation
3. Bonding protocol
4. Matrix application

1. Isolation

Whilst rubber dam use is taught and practiced routinely at dental school, many dentists quickly fall into a habit of only using such isolation for endodontic treatment. Lack of familiarity with rubber dam can lead to reluctance to use it for posterior composites. However, the reluctant clinician should practice the use of a “one-shot” technique where the barrier is stretched over the frame and a winged clamp is used. This technique can be very fast and simple, often taking less than a minute to isolate one or two teeth and a couple of minutes for a quadrant. The advantages of rubber dam use outweigh the negatives of blood and saliva contamination which ruin bonding. The use of rubber dam should be practiced for the vast majority of cases.

2. Tooth preparation

Tooth preparation should be limited to access and removal of any failed restoration and caries. The cavity preparation should be rounded in form with no sharp internal angles so as to prevent potential stress concentration and to make it easier to adapt the composite material to the cavity. Placement of bevels on the vertical walls of the box of a Class II restoration has been shown to improve adaptation and reduce microleakage. Bevels on the occlusal surface only seek to disguise margins and may have a detrimental effect in terms of thin sections of composite on the biting surface, which may fracture with time.

3. Matrix application

The use of conventional “passive” type matrix bands, such as Tofflemire and Sykeland types (which are suited to amalgam restorations), are often found to be inadequate for posterior com-
The 1st flowable bulk-fill base

- Bulk-fill in increments of 4mm without layering
- Excellent cavity adaptation reducing post-operative sensitivity
- Provides excellent self-levelling properties
- Already thousands of users

Changing dentistry 4mm at a time
a great deal of boring and wedging apart of the teeth to produce adequate contact points, and the anatomical interproximal contour is often not accurately reproduced. The best way around this problem is with the use of a sectional “active” matrix system such as the V3 Ring System or the Palodent system. This comprises a very thin sectional metal band which is wedged and then held in place with a ring, not dissimilar to a rubber dam clamp. This ring, as well as holding the band in place, will push apart the teeth sufficiently so that when ring and matrix are removed, there will be a good tight contact point/area.

4. Bonding protocol
Understanding proper dentine bonding technique is essential. Enamel bonding is well understood and relatively simple and reliable. Dentine bonding, however, has undergone numerous changes over the past 15 years with several generations now available. The range of systems can be a little bewildering; however, the use of high quality dentine bonding systems, such as Optibond Solo or Prime & Bond NT, if used correctly, will lead to good results.

Poor bonding technique can lead to post-operative sensitivity and premature failure of the bond leading to microleakage and secondary caries. The most important thing is to read the instructions; it is amazing the number of people who don’t! Each generation of bonding system has particular peculiarities to it, such as having to shake the bottle before use, or to having to keep the product refrigerated, it is therefore essential to read the instructions and to follow the protocol correctly for optimal results.

Featuring, precision control

As one of the world leaders in handpiece technology, NSK can help clinicians perform safer, more accurate root canal procedures with their range of endodontic handpieces, micromotors, Ultrasonic scaler and apex locator.

NSK’s Endo-Mate TC2 has a large LCD screen, simple 5-key operation and a lightweight, cordless handpiece ensuring it is easy to use even during the most delicate endodontic procedures. The Auto Reverse & Alarm Function sounds an audible alert when the preset torque level has been reached, allowing the operator to unload the file even before the Auto Reverse function engages. Endo-Mate TC2 also features 5 programmes for different file systems whilst supporting most major brands of Ni-Ti files.

Specifically designed for use with Ni-Ti files from all major suppliers, the ENDO-MATE DT endodontic micromotor delivers complete versatility with an advanced memory able to store up to 9 speed and torque settings. The ultra-slim, lightweight handpiece is the ideal alternative to hand-held root canal instruments, delivering an extremely low level of noise and vibration that effectively promotes patient comfort whilst reducing hand fatigue. ENDO-MATE DT can be connected directly to a wall outlet or used with a rechargeable battery. A large LCD display offers higher visibility for instantaneous recognition of the micromotor’s status.

NSK’s apex locator, iPex which accurately measures the length of any root canal, including dry, wet and bloody canals, helps clinicians perform safer, more accurate root canal treatment.

NSK’s Varios 970 Ultrasonic scaler incorporates the brand new NSK/iPex control board with the very latest, most advanced, standards in auto feedback technology, making the performance smoother and more efficient when used for endodontic shaping. The Varios is also available as a built-in unit - Varios 170, which can be used in conjunction with NSK’s new MultiPad to easily control all its functions.
