**A simplified, minimally invasive sinus lift technique using autogenous bone**

By Drs. Samuel Lee and Grace Lee, DDS

Implant dentistry in posterior maxilla has often been a challenge due to pneumatized sinus. Bone grafting in sinus cavity is known to be very unpredictable with good long-term success. There have been several surgical techniques suggested for sinus lift such as lateral window (Cald-Well Lue), osteotome (Summer's) technique, Hydrolic sinus lift, etc. However, lateral window techniques some what invasive with many complications and postoperative pain involved. In contrast, Summer's and Hydrolic Sinus procedures are less invasive, but more technique sensitive. This author developed a very simple and predictable way to lift Schneiderian membrane and at the same time collect autogenous bone. This procedure can be done with or without flap with minimal postoperative discomfort. The author named the procedure ‘The WaterLESS’ technique and was awarded the table clinic award at 2007 American Academy of Implant Dentistry’s annual meeting at Las Vegas.

Conventional implant osteotomy technique utilises ample amount of irrigation at 800-1600 rpm in order to prevent overheating bone. However, utilisation of water washes out bone particles collected at implant drills. In contrast, WaterLESS technique is drilling at 40 rpm at 50 Ncm without irrigation. This low speed prevents bone heating, allows bone collection, and increases tactile sensitivity. Using the right shape burs and without water at low speed, implant clinicians can collect autogenous bone as much as 0.5 cc per osteotomy site in d3 bone (Figs. 1a and 1b).

With conventional osteotomy technique at high speed, the surgeon can’t feel anatomical structure of bone, and Woodless Schneiderian membrane is more forgiving. WaterLESS technique allows dental surgeons to differentiate the sinus floor, which is more highly dense cortical bone, by tactile sensitivity. With aid of radiograph, approximate length to the floor is calculated and implant drill is used to

**Fig. 1a:** Collection of autogenous bone from osteotomy site.

**Fig. 1b:** Approximately 1 cc of autogenous bone collected from two 1X10 mm D3 bone osteotomy sites.

**Fig. 2a:** WaterLESS technique allows surgeon to feel the lingual plate, therefore preventing perforation at lingual of posterior mandible.

**Fig. 2b:** WaterLESS technique allows surgeon to feel the buccal plate, therefore preventing perforation of facial plate at anterior maxilla or mandible.

**Fig. 2c:** WaterLESS technique allows surgeon to feel resistance when roots are touched, so that the surgeon can reangulate the implant to avoid complications.

**Fig. 2d and e:** 1A nerve at 113 area is located buccally and superiorly. With careful planning 3X10 mm implant placed lingually by passing 1A nerve.

**Fig. 2f:** Reduced intervals. Implants inserted into extraction sockets will heal predictably with clinically significant bone quantities and preserving the soft tissue structures.
reach just before the sinus floor with WaterLESS technique. While making the osteotomy, autogenous bone is collected for later use (Fig. 1).

Use series of tapping drill to condense the bone laterally if the bone is too soft (Fig. 4a), then elevate the floor with larger tapping drill going just 1mm deeper (Fig. 4b).

Sinus membrane has some flexibility, so often it allows 1 mm of elevation without perforation. Once floor is fractured, the author packs gauze into the sinus to elevate the Schneiderian membrane, then remove the gauze and adds resorbable membrane. This author also invented 'roll technique' to introduce resorbable membrane into the sinus cavity to better maintain grafts (Figs. 5a, b).

Fig. 4a: Condensing bone due to weak bone

Fig. 4b: Breaking the floor of sinus with larger tapping bur (going just 1mm deeper). Membrane can be visualised and it will go up and down when patient breathes.

**Mediterranean Master Program in Implantology**

gIDE / UCLA

One year Master Program 2008/09

206 hours / 16 days of clinical training in 4 sessions.
60 hours / 4 modules of e-learning curriculum from world renowned clinicians and scientists.
3 hands on workshops and 14 Live Surgery demonstrations.
8 exam assessments.
12 Hours of video surgery on iPod touch 16GB (Apple).
2 case presentation, 5 reviewed by faculty

**Session I**
2008, November 19-21
In Athens, Greece

**Session II**
2009, January 20-23
Day 1, 2 and 3
In Athens, Greece

**Session III**
2009, May 15-18
Day 4, 5, 6 and 7
In Athens, Greece

**Session IV**
2009, September 14-17
Day 8, 9, 10 and 11
In Athens, Greece

2009, December 12-15
In Los Angeles, USA

There is no training similar to this 1-year Certificate Program in Implant Dentistry with a didactic, a hands – on program and live surgery from the world’s leading clinicians and educators.

- Between session 1 and 2 e-learning (A-Z in Implant Dentistry / 24 hours course followed by exams)
- Between session 2 and 3 e-learning (Advanced Implant Therapy / 34 hours course followed by exams)
- Between session 3 and 4 e-learning program (Esthetic Implant Dentistry and New Advances / 12 hours course followed by exams)

After membrane placement, bone graft is added slowly using a non-end cutting bur in reverse direction. This pack technique packs bone laterally (Fig. 6).

Figs. 5a and b: Resorbable membrane is inserted under elevated sinus membrane. This author prefers to use Lambone from Pacific Tissue Bank, Calif.

Fig. 6: Packing bone in reverse direction to distribute bone laterally within sinus cavity after packing and removing sterile gauze.

Wide diameter or implant with larger platform than body is ideal for internal sinus lift, since larger platform will resist the implant accurately going into the sinus in case of low primary stability. The author
preference for a palatal incision when performing this procedure. However, in severely resorbed ridge, greater palatine artery can be quite close to incision line, so caution is recommended.

The reason for palatal incision is that if the perforation of sinus membrane is occurred, simply we can close up the flap and avoid chances of getting oral antral fistula. Placement of non-resorbable membranes recommended for thin gingivaltypen and thin sinus floor. Then simply reattempt the same procedure in 2-3 months depending on the size of perforation.

My neck feels so much better today thanks to my Optergo Solution!

65% of dentists have neck or back complaints which are mainly caused by incorrect working postures*

Now there is help.

Try Optergo’s unique spectacles and loupes and you will notice the difference immediately. The special optics with built-in prisms make it possible for you to sit in a correct working posture without over bending your neck or straining your eyes.

Planning for success: the restorative/surgical interface

By Dr David R Bloom, Dr Jay Padayachy and Dr Guy McLellan

Historically, the surgical placement of dental implants (especially in the anterior maxilla) has relented solely on where the surgeon felt he or she was able to place them, depending on the location of the bone itself, rather than on where the restoring dentist would ideally like them to go. The longevity of implants is now so assured that just having an implant in function is no longer regarded as a success, unless it fits in with the rest of the dentition, both in terms of position, soft-tissue health and aesthetics. The management of the soft tissue has become crucial to the overall success or otherwise of a case.

Preparing for treatment

It doesn’t matter whether the dentist is placing and restoring or just restoring and referring for placement. What is paramount is correct diagnosis and treatment planning. This all begins with a comprehensive examination, digital radiographs and digital photography, study models, and understanding or managing the patient’s expectations.

If we look at the placement of a single implant in the anterior region (this is demonstrated in the case studies), we need to consider:

1. When was the tooth lost? This is relevant to whether there is enough bone in both the vertical and horizontal planes. Whilst vertical defects may require a bone graft a horizontal (bucco-lingual) defect may be amenable to a connective tissue graft as long as the ridge is not too knife-edged thus contraindicating ridge expansion. Thus bone sounding and a sectional CT scan may be appropriate.

2. If the tooth is present, is there infection and how much bone has been lost? This could necessitate a period of healing prior to implant placement and thus require temporisation. Immediate placement (at time of extraction) and immediate loading (using an abutment, temporary or permanent, to connect a temporary crown at implant placement) are becoming more commonplace, which we shall discuss below. There are even prefabricated permanent abutments available and some of these actively encourage tissue maturation – Nobel Icyv.

Consider final positioning

When planning, it is important to consider the final positioning of the restored implant itself. For example, work backwards from positioning to placement, rather than placement to positioning. Thus, a wax-up may be required as you would do for a smile-design case or a large class-four composite build-up. This will demonstrate where the abutment needs to emerge from the soft tissue and hence the implant requires to be placed and if there is a need for an angled abutment fixture head. From this, a surgical stent is made to allow accurate placement of the implant.
Immediate placement can be contra indicated if infection is present, but some authors advocate thoroughly curetting the socket and using tetracycline paste to limit post-operative infection, allowing immediate placement even in cases with peri-apical granulomas. It is the author’s preference, however, to delay placement in these cases by six to eight weeks.

If good insertion torque (55Ncm) can be achieved, one can consider immediate loading. Some palatal inclination of the apical one-third of the implant can make this more easily achieved and some newer implant systems, such as the Nobel Active, also facilitate good insertion torque.

If it is possible to immediately load, one can use a laboratory-constructed provisional cemented onto a temporary metal abutment post and temporary coping, but ensuring that the provisional is not in occlusion. Alternatively, if required, temporaryisation can be achieved with a flouche type bridge if the implant is not to be immediately loaded. A flouche bridge is favoured over a Mary Land as this is easier to remove and re-cement as necessary.

Some authors will only make this lab-made temporary crown and use it as above if immediately loading OR convert this crown into a pontic and use fibre technology to cement it as a temporary bridge if the correct insertion torque cannot be achieved. This allows a ‘get out of jail card’ if the implant cannot be immediately loaded. One of the stated advantages of not repeatedly unscrewing healing caps or temporary abutments is that there is less disturbance of the bemi desmosome soft tissue attachment.

Bulking soft tissue

At the time of implant placement the soft tissue can be bulked out if required with a connective tissue graft (free or pedicled) or using guided bone regeneration. A more simple technique is to pack Bio-oss particles into the buccal tissues without a membrane. Although it is unlikely that much functional bone will be formed, the particles are stable over the long term and act as a ‘filler’. Larger defects are treated with biss oss and double layer Bio-gide technique. The importance here is to achieve tension free closure with advancement techniques and periosteal release. This will require a two-stage approach.

If the implant is left for three to six months to integrate, a further appointment will be required to expose the fixture head and to place a healing cap. At this stage, a further graft or taking a roll of palatal tissue can be used. This enables the surgeon to refine the soft tissue contour and give a root form appearance to the soft tissues. The surface is des-epithelialised and a reverse ‘D’

**Instant Gratification for Denture Patients**

IMTEC’s Sendax MDI Implant System offers a revolutionary one-hour, one-stage solution for long-term denture stabilization. This immediate loading mini dental implant system utilizes a patented, flapless placement protocol and works with the patient’s existing denture. The versatile MDI implant family includes the 1.8 and 2.1mm implants with standard thread design and the 2.4mm MAX thread for softer bone.

**IMTEC Mini Dental Implant System**

IMTEC’s Sendax MDI Implant System offers a revolutionary one-hour, one-stage solution for long-term denture stabilization. This immediate loading mini dental implant system utilizes a patented, flapless placement protocol and works with the patient’s existing denture. The versatile MDI implant family includes the 1.8 and 2.1mm implants with standard thread design and the 2.4mm MAX thread for softer bone.

**MDI Hybrid Implant 2.9mm Implant System**

This one-piece implant enables placement with a procedure much like the familiar MDI placement protocol, using MDI instrumentation, making it the most minimally invasive implant of its size.
