More comfort, less invasion

New expansion techniques mean dentists can offer the patient more comfortable therapies.

Dr Derek Mahony looks at the history of these kinds of treatments and how they’ve evolved.

Edward H Angle dominated orthodontic armamentarium, diagnosis and treatment planning for almost 50 years until Charles Tweed successfully challenged his mentor’s non-extraction mantra. The ensuing diagnostic regimen used by Tweed, however, proved to have serious limitations and clearly resulted in the extraction of too many teeth. This caused a subsequent deterioration of soft-tissue appearances of patients that neither they, nor their doctors liked. This article will describe and illustrate how new expansion techniques differ qualitatively from those of Angle, and how these techniques offer patients and doctors less invasive and more comfortable therapies which do not jeopardise facial appearances.

How it began

For the first third of this past century, orthodontics found itself dominated by one man, Edward H Angle, with the resultant intellectual stagnation that arises from such monomaniacal control. This recognition in no way detracts from Angle’s contributions – notably his clear and simple classification system along with the edgewise bracket. Both of these inventions have endured for a century, and that is no mean achievement in any scientific discipline. Nevertheless, orthodontists’ unquestioning acceptance of his limited diagnostic and treatment planning regimens hindered the advancement of this discipline more than it helped, and the last half of this past century was spent trying to overcome the stupor of the first half.

Angle’s influence continued until an apostate student of his, Charles H Tweed, had enough courage and objectivity to challenge Angle’s non-extraction scheme. It wasn’t a tremendous leap of intellectual power. Tweed simply and honestly recognised that when 100 per cent of your patients relapsed, there might be something wrong with the diagnosis and/or treatment planning.

Courage to object

Dr Tweed acted appropriately in the face of this challenge – quite unlike the ancient dentist who chided a young colleague who was describing his meticulous technique of endodontic filling to the monthly assembly of dentists. The old man explained his own technique that used a simple matchstick sharpened with a pocketknife and then jammed into the canal. When the young dentist asked if a lot of these root canal fillings didn’t subsequently fail, the older man replied, ‘Every damn time!’

Dr Tweed tired of those orthodontic abscesses and, unlike his peers, sought to correct the deficiencies he saw in Angle’s philosophy. Some would say that he overcorrected, but that said, we must pay homage to anyone who has the skill and temerity to successfully challenge a mentor and his minions.

Nevertheless, I don’t think that Tweed would have ever been able to deliver his paper describing his extraction technique had Dr Angle still been alive. Angle’s influence over the society that bore his name was too immense to permit such
hubris from a young upstart. But as Samuelson, the MIT econo-
mist, once noted: ‘Science pro-
gresses slowly – funeral by fu-
neral.’ And so it was and is in orthodontics.

Non-extraction philosophy

Aside from the edgewise bracket and the classification system, Angle’s most enduring legacy has been his belief in non-extraction therapy. Angle had unsuccessfully experimented with premolar extrac-
tions while using his ribbon-
arch appliance, but he never solved the problem of parallel-
ing the roots to prevent the ex-
traction spaces from opening. If he couldn’t do it, then, ergo, no one else could, and this resulted in a virulent opposition to any extractions and an insistence upon enlarging the arches to ac-
commodate all of the teeth.

This dogma stayed domi-
nant for several decades until Tweed advocated the extraction of premolars based on his diag-
nostic triangle, which was the first systematic treatment plan-
ing strategem orthodontists had. Tweed received corrobora-
tion simultaneously from an-
other former Angle protégé in Australia, Raymond Begg, who had studied aborigines and con-
cluded that nature intended for enamel to wear. He decided that orthodontists could mimic na-
ture by extracting teeth prior to orthodontic therapy. The Tweed and Begg Extraction Philoso-
phies eventually prevailed and remained uncontested for some time.

Several years past before Holdaway published his arti-
cles that suggested the soft tissue as the determining feature of di-
agnosis. This disputed Tweed’s narrow diagnostic regimen that focused on the mandibular inci-
sor and totally neglected the soft tissue. Tweed’s triangle set in mo-
tion a trend that emphasised more prudence in the extraction of teeth. Soon others added their discoveries regarding soft tissue and the maxillary incisors as main determinants of diagnosis and treatment planning.

Keeping a record

From the inception of this spe-
cialty, with Dr Angle, diagnosis never had too much importance because everyone received the same non-extraction treatment with the same expansive appli-
ance. The marvel of it all is that the collection of orthodontic records never became important. A few months ago, an orthodon-
tist boasted that since invoking a different treatment regimen, he was treating 98 per cent of his pa-
tient’s non-extraction. One was tempted to ask if he still took records because with diagnostic certainty such as that, records are clearly redundant. Orthodontists shouldn’t waste patients’ time and money taking impressions, cephalometric X-rays or doing treatment simulations if all treat-
ment plans are essentially the same. One doesn’t need orthodontic records to come to such a preconceived conclusion.

Obviously, this one-size-fits-all approach does not benefit patients a hundred years ago, and it doesn’t in our own age. But such simplicity continues to be an enormous advantage to many orthodontists. Orthodontists pride themselves in being scientific and without doubt they receive good training in the scientific method; but it takes very little anecdotal information to eclipse the scientific judgment of many in the profession. It is probable more right than he knew when he said, ‘The brain is not an organ of thinking but an organ of survival like a claw and fang. It is made in such a way as to make people capable of thought which is only advantage.’

No matter how spectacularly orthodontic therapy changes, it will benefit our patients minimally if we do not have a corresponding improvement in our diagnostic and prognostic knowledge. This remains the number one imperative for those who practice orthodontics. Orthodontists should view any new therapy unaccompanied by equally sophisticated diagnostic knowledge suspiciously. Patients have already received far too much orthodontic treatment and far too little diagnosis.

**Instrumentation**

The first attempts to correct malocclusions used simple large arch wires ligated to the malposed teeth. Pierre Fauchard of France developed the precursor of the modern appliance—expansion arch (Figure 1).

This arrangement gave only tipping control, in one dimension and was inadequate for controlling rotations. In 1887, Angle introduced the E-arch, for example, expansion arch that used a laval wire supported by clamp bands on the molar teeth which ligated to the other teeth (Figure 2).

Metallurgical developments by the early 20th century allowed clinicians to encase all of the teeth with bands and solder at-tachments that could control the horizontal rotations. Angle developed a popular attachment known as the pin and tube attachment in 1911 (Figure 5), and it satisfied many of the requirements of clinicians; but this demanded unusual dexterity, patience and skill, so dental clinicians were very interested in a ribbon arch attachment (Figure 4), which Angle introduced in 1916. It provided good control of the molar teeth and became popular quickly. The ribbon arch attachment also provided minor but practical trimming such as rotating wings, parallel roots and artistically position teeth, while Angle’s invention confirmed Angle’s modest claim that it offered the ‘latest and best in orthodontic mechanisms.’

Innovators have added minor but practical trimmings such as rotating wings, parallel roots and artistically position teeth, while clinicians throughout the United States and eventually eclipsed other useful orthodontic appliances such as the McCoy open-tube appliance, the Atkinson universal appliance and the Johnson twin-wire attachment.

The universal application and durability of the edgewise bracket confirmed Angle’s modest claim that it offered the ‘latest and best in orthodontic mechanisms.’ Innovators have added minor but practical trimmings such as rotating wings, parallel roots and artistically position teeth, while Angle’s invention confirmed Angle’s modest claim that it offered the ‘latest and best in orthodontic mechanisms.’

Other than adding wings and doubling the bracket to make the popular twin edgewise bracket, Angle’s invention has remained basically unchanged. Holdaway suggested angulations for brackets to help set anchorage, parallel roots and artistically position teeth, while Lee built some anterior brackets with the ability to torque incisors. But it was Andrews that was to develop an appliance that would apply first, second and third-order movements to the teeth without making changes in the wire—hence the straight wire appliance.

Preadjusted orthodontic appliances have dominated the profession for the past 50 years, and the belief in them shows little sign of abating even though many have questioned the one-size-fits-all idea.

And back again

The publication of Frankel’s work with functional appliances illustrated significant enlargement of dental arches and reawakened an interest in non-extraction therapy. Nevertheless, Frankel mechanics required the use of removable appliances, and that didn’t resonate well with many orthodontists or their patients. After a brief flurry of interest in the United States, few clinicians continued to use the Frankel appliance on a regular basis.

Nevertheless, the successful use of orthopedic appliances alerted orthodontists to the possibility of increasing arch widths and arch perimeters with minimum forces. Although mandibular canines offer significant resistance to expansion, mandibular premolars and first molars often demonstrate substantial and stable expansion. Brader hinted at this with his work on the tri-focal ellipse arch form, but he didn’t follow through about how this might give wider and more accommodating arch forms.

Low-force titanium coil expanders have shown their ability to develop arches laterally, and recently Damon has suggested that low arch wire forces, coupled with a passive tube and a small wire-to-lumen ratio, enable teeth and their accompanying dental tissue to expand in all planes of space. Damon feels that using small, low-force wires such as those of Copper Ni-Ti (Ormco Corporation, Orange, CA) achieves ideal biological forces proposed long ago by several investigators.

Self-ligating brackets that essentially form a tube developed several decades ago with the Ormco Edgelo by the first, closely followed by the Speed brackets. Both of these early self-ligating systems suffered from the fact that the Straight-Wire appliance phenomenon debuted at the approximately the same time, plus a lack of appreciation for what the newer titanium wires could achieve.

**Trial and error**

Damon has persisted since 1995 with his version of a self-ligating bracket (Figure 8) and has fundamentally changed the types of arch wires and the sequence in which clinicians use them. His experience has shown that with many patients he can often eliminate distalisation of molars, extractions (excluding those needed to reduce himaxillary protrusions) and rapid palatal expansion. He offers compelling clinical evidence of doing this with consistency.

The Damon bracket is essentially a tube designed with the right dimensions to foster sliding mechanics where needed and enough play in the system for torque and rotational control using the larger cross section wires. Damon starts cases with a large lumen arch wire slot and .014 or smaller diameter hi-techology arch wires. Starting cases with a large dimension passive arch wire slot and small diameter wires diminishes the divergence of the angles of the slots. This lowers the applied force and binding friction.

The most logical questions readers could propose would be why has Damon shown successful expansion whereas Angle didn’t? The quantity of expansion probably differs little,

Are you Smart enough?

SmartCem2 is a self-adhesive cement with the perfect combination of handling and strength

- Self-adhesive, eliminating the need for separate bonding step, saving you time
- Very low moisture solubility and expansion, increasing its indications and helping reduce patient sensitivity
- Designed for many cementation applications, including cementation of indirect restorations; ceramic, composite and metal inlays, onlays, crowns, bridges and posts
- Dual barrel automix syringe system, for consistent mixing and easy delivery
- Available in five shades: Light, Medium, Dark, Translucent and Opaque

For a FREE demonstration in your practice, call +44 (0)800 072 3313 to arrange an appointment

For more information on SmartCem2, please call our freephone number or email us:
