20 years of membrane-protected bone regeneration

A report

**Authors:** Jiaoshou (Prof.) Dr Frank Liebaug & Dr Ning Wu, Germany

**Fig. 1** Example for different non-resorbable, titanium-mesh-reinforced ePTFE membranes, which are available in different forms and sizes depending on the manufacturer.

**Fig. 2** Close up clearly shows the titanium-mesh reinforcement in the non-resorbable membrane material.

_Dental implantology has developed_ to a reliable and successful clinical routine procedure for all those cases where an adequate bone material is available. But this precondition is not always met. Nevertheless, today also patients with a bone situation which is not optimal for implant insertion do wish an improvement of function and aesthetics—they actually consider this to be granted.

**Introduction**

The use of barrier membranes for the regeneration of bone defects has changed dental implantology in the course of the last 20 years a lot. The principle titled as "membrane-protected bone regeneration" was first described by Hurley et al. in 1959. Already in the 1960s, a research group around Bassett and Boyne tested and described micro porous cellulose acetate laboratory filters (Millipore) for the treatment of cortical defects on long bones and the osseous reconstruction of the jaw. The basic idea of the authors was to use filter material for the isolation of bone defects against the cells of the adjacent, fibrous soft tissue and to create an appropriate milieu for osteogenesis. However, these pioneering studies did not immediately lead to a broad clinical application of barrier membranes on patients. Actually, the clinical possibilities of the membrane technology were not recognised until the early 1980s where the research group around Karring and Nyman systematically investigated the use of barrier membranes in different experimental and clinical studies on periodontal regeneration.

Already at the end of my studies about stomatology, especially the possibilities for periodontal regen-

20 years of expertise, reliability and innovation in implantology – worldwide. Say yes!
I was greatly interested in implants. At that time, great hopes were placed on the so-called GTR (Guided Tissue Regeneration) technique for treating extensive periodontal bone defects. A few years later, the membrane technique was tested as part of experimental studies on bone regeneration for larger alveolar ridge defects. Based on the studies' promising findings, the clinical use of membranes on implant patients started in the late 1980s (Nyman et al. 1990).

Despite this, it was not before the beginning of the 1990s until the discussion of this application found its way to congresses. From this time, works by Wachtel and Bernimoulin are to be named (Wachtel 1990, Wachtel and Bernimoulin 1991). In 1994, I purchased the first book dealing with this issue by Buser, Dahlin and Schenk for my private, scientific library. Under the title “Guided Bone Regeneration in Implant Industry”, the authors published after five years of intensive experimental and clinical preparation the first English-speaking issue of this book in 1994, which could arouse a large interest for this topic on my side as well as among implantological experts. Since then, the GBR technique has constantly developed.

Aims of membrane application

- Undisturbed regeneration of bone through a barrier function against the adjacent soft tissue.
- Avoidance of graft resorption particularly in autologous bone transplants.
- Protection against loss or dislocation of bone or bone graft substitute particles.
- Protection of the regenerate in case of wound dehiscence.

Depending on the used membrane type, the desired bone regeneration is given the required time and rest in a defined area. Especially the reservation of space volume defined by a surgeon can be perfectly ensured by the use of titanium-reinforced membranes (Figs. 1 & 2). Before the insertion into the operation area, these membranes can be tailored and also bended, as shown in Fig. 3 only exemplarily.

From 1994 to 1996, I thus used non-resorbable, titanium-mesh-reinforced membranes from the company W. L. Gore and Associates, Inc. USA, at first. Although, I as an operator was very satisfied with the clinical outcomes of the bone regeneration in

Implant planning made easy

Planmeca PlanScan®

Planmeca ProMax® 3D

Planmeca Romexis® software offers a completely integrated and digital workflow for modern implantology. From intraoral scanning to easy prosthetic design and realistic implant libraries, the most sophisticated implant planning tools are just a few mouse clicks away.

- All the scanned and design data for prosthetic works is immediately available and can be mapped with the patient’s CBCT data
- Use crown library or patient-specific crown from CAD system
- Verify the implant plan with verification tool
- Order surgical guide directly from the software
- Share data easily with partners through Planmeca Romexis® Cloud image transfer service

94 per cent of the cases, for most patients the necessary second surgery was subjectively more burdensome than the first one. As a questionnaire of my patients had shown, they were relatively satisfied with the therapeutic measure—meaning the first surgery and the overall treatment. But there was also a remarkable number of patients who considered the second surgery for the removal of the non-resorbable membrane materials as disturbing and even more burdensome than the first one (Tab. 1). This has improved with the introduction and application of resorbable ePTFE membranes, which were and still are available in different configurations on the dental market—depending on the field of application. As long as there was no surgery for membrane removal, the patients were relatively satisfied with the therapy from the beginning to the end (Tab. 1). The handling of a titanium mesh reinforced ePTFE membrane with its complete plastic coverage puts enhanced requirements on the oral surgeon depending on the area of

**Recommended treatment before use**
- membrane-cutting to defect size

**Processing before use**
- cut to size, can be applied wet and dry
- cut to size, apply dry, fast hydrogenation
- no further processing needed

**Recommended fixation**
- unnecessary, pin or suture if needed
- ns.
- sticks well to defect, additional fixation with titanium-pin or double-layer-technique (Buser) in case of bigger defects

**Available sizes**
- 15 x 20 mm
- 20 x 30 mm
- 30 x 40 mm
- 20 x 20 mm
- 25 x 25 mm (6,25 m²)
- 30 x 40 mm (12,0 m²)

**Price per membrane**
- 15 x 20 mm: 90 Euro
- 20 x 30 mm: 110 Euro
- 30 x 40 mm: 165 Euro
- 12 pieces = 200 Euro from 122 Euro

Tab. 3
Ilesion. The plastic and de-energised coverage often proves to be difficult (Tab. 2). However, the clear room stabilisation and the volume preservation (Fig. 3) are particularly to be highlighted as the core advantages.

For the sake of completeness, I want to mention my use of a direct applicable GTR barrier for the coverage of periodontal bone defects—which is especially indicated for an infestation of bifurcation—on the protection of augmentation material. In the then dental market, this barrier was available under the name Atrisorb® of the company Atrix Laboratories, Inc., Fort Collins, USA. Although the clinical healing process was unremarkable, a dimensional stability of this viscously applied barrier materials after hardening was not traceable. At least, there was no dislocation of particles from the materials placed into the defect. Due to the few patients treated in this way, these were not included into the evaluation of the questionnaire.
Already since 1996, I increasingly switched to the clinical application of collagen membranes. Besides the effective barrier function, the good wound healing properties were and still are the reason why I am using these materials almost exclusively for my patients’ treatment now. Both the handling as well as the patient compliance is in most cases superior to the old methods using titanium mesh reinforced ePTFE membranes (Tab. 1 & 2).

As Plöger described in 2003 already, natural collagen membranes do influence tissue integration in a positive way. Amongst our treatments, only 1.5 per cent of the cases of membrane application showed low dehiscence after eight days and about 5 per cent after 30 days. This was a revolutionary improvement compared to the titanium mesh reinforced, non-resorbable as well as resorbable ePTFE membranes. Under a local antiphlogistic treatment, the lowly exposed collagen membranes do heal without complications, whereas the other membrane types need be removed promptly in case of a wound dehiscence. In principle, all membrane expositions or wound dehiscence are clinically controllable. But they also require the frequent scheduling of patients and at least weekly follow-ups and wound cleaning, which is reflected by a lower patients rating (Tab. 1). For this, the reason can be seen in the fact that collagen chemo-tactically works on fibroblasts and thus enhances the primary wound closure. Today it seems to be undisputable that it supports the development and stabilisation of the wound coagulum and promotes the proliferation, migration and adhesion of cells. Furthermore, when reducing the membrane materials there is no need to fear irritations of the tissues or the desired regeneration processes, which in contrast can occur for synthetic materials. In Table 3, the membrane materials used in my practice from 2001 until 2014 are listed with their different properties.

In the direct clinical comparison, the handling of the native collagen membrane—in our case Bio-Gide® by Geistlich Pharma AG, Wolhusen, Switzerland—was remarkably easier. After unpacking out of the delivered sterile box, this material can be tailored without problems and thus adapted to the defect and configuration size (Figs. 4–6). Soaking or moistening with any liquids before application is not needed; shortly after the application, the membrane material becomes saturated with the surrounding blood and the below defect area (Figs. 7 & 8). Regardless of autologous bones or bone graft substitutes of different origins, the adhesion to bone walls and the adaption to the augmentation material is much better than for synthetic membranes—if it is possible at all. Thus, I used resorbable pins for membrane consolidation only in the beginning of my augmentative work. Today, I am adapting the barrier material below the adjacent periost (Fig. 7). However, collagen membranes do always need dimension stable bone graft substitutes or autologous bones to prevent the room volume from collapsing.
I AM A FAN
like most of my colleagues.

Dr. Leyli Behfar | Specialist in Oral Surgery

CAMLOG is my first choice when it comes to dental implants. With their high-precision implant systems, I find an answer for every indication. Implantations can be performed easily, efficiently and with excellent quality standards. CAMLOG is an inspiring partner in many ways – and that is getting around. www.camlog.com

a perfect fit™
If the operator can achieve a primary and de-energised wound closure, fissure dehiscence is a rare exception and possibly due to subjective patient factors. Usually, I use 5/0 or 6/0 fissure material in augmentation surgery, whereby the Bio-Gide membrane, which I am using oftentimes, is available in the dimensions 13 x 40 mm, 25 x 25 mm or even 30 x 40 mm. Thus, the operator has an option for almost every indication and can choose the most economic, i.e. most priceless option, which is also in the patient’s interest.

I must not forget to point out the remarkably good material properties of this membrane regarding tensile strength and foldability, which is not granted for every competitor. Thus, I often perform external sinus lift operations with very small lateral bone space, whereby I fold the membrane—in the same way as a model ship is inserted into a bottle—and then unfold it before it becomes saturated with liquid. In this way, the Schneider’sche membrane in the paranasal sinus is stabilised for a long time and a perforation of undesired dislocation of augmentation material is prevented successfully (Liebaug & Wu, 2011).

**Conclusion**

Without the application of augmentative treatment methods—particularly the membrane protected bone regeneration—I would have helped only few patients to get a fixed or high-quality implant-supported dental prosthesis in the past 20 years. In my therapy concept, a successful dental implantology begins already or at best with the socket preservation and ridge preservation simultaneously to the tooth removal. But these measures do make sense when afterwards a conventional prosthetic rehabilitation with fixed bridges or combined fixed and removable telescopic or bed-load prosthesis will be planned. The application of barrier membranes—particularly collagen membranes—has developed to a very reliable and successful clinical routine procedure for all those cases where an adequate bone material in height and width shall be generated for later therapy measures.
