Er,Cr:YSGG treatment of gingival melanin hyperpigmentation

Authors: Dr Habib Zarifeh, Dr Monique Hanna & Dr Dany Salameh, Lebanon

Introduction

In the past few decades, the improvement of intraoral soft tissue aesthetics has become a significant element in clinical dentistry, including gingiva, which is the most commonly affected intraoral tissue, causing an unpleasant appearance. In fact, oral pigmentation is a discoloration of the oral mucosa or gingiva due to several exogenous and endogenous factors, such as drugs, heavy metals, genetics, endocrine disturbance, and inflammation.  

Also, melanin produced by melanocytes can cause melanin pigmentation, varying from light to dark brown or black, according to the quantity and distribution of active melanin in the tissue. Oral pigmentation occurs in people of all races. Indeed, oral pigmentation increases in darker-skinned individuals. However, there is no difference in the number of melanocytes between fair-skinned and dark-skinned people. The variation is related to differences in the activity of melanocytes.

Several procedures have been suggested for gingival depigmentation, varying from bur abrasion, surgical scraping, cryotherapy, and electrosurgery to laser therapy. Various lasers, such as carbon dioxide (CO\textsubscript{2}) laser, Nd:YAG laser, semiconductor diode laser, argon laser, Er:YAG laser and Er,Cr:YSGG laser, have been indicated as an efficient, pleasant and reliable method with minimal postoperative discomfort and faster wound healing for depigmentation procedures.

A healthy 39-year-old male with no previous surgical history and no allergies and no current medication had a chief complaint of dark pigmented areas in the anterior part of the upper and lower maxillary gingiva, stating that he was an occasional smoker. During the clinical examination, no abnormalities nor gum disease were revealed, but deep melanin pigmentation in the upper and lower mucosa, along with the marginal gingiva, was noticed. This lead to a dark gum colour and by consequence a less aesthetic smile (Fig. 1). Laser depigmentation procedure was planned. The process was explained to the patient and his consent obtained.

Digital images of the pigmented gingiva were taken preoperatively and on postoperative visits. Laser safety protocols were respected. The patient was treated with local anaesthesia. A Er,Cr:YSGG laser of...
2,780 nm was used with the following parameters: gold handpiece, Z6 tip, 60% water, 40% air, H Mode, 3.0 W, 20 pps, direction of the tip was slightly parallel or with 30 degree to the gum surface (Fig. 2), up to the second premolar on both the right and left side of the maxillary and mandibular anterior gingiva. We worked at a distance of 2 to 3 mm in non-contact mode with 30 degrees to the gum surface, with slow shaving movements until the removal of the pigmented layers of the epithelial cells and the connective tissue to remove melanin pigmentation (Figs. 3 & 4).

After the total removal of the pigmented layers of the gum (Fig. 5), an additional application of the Er,Cr:YSGG of 2,780 nm was done using different parameters: gold handpiece, Z6 tip, 0% water, 0% air, non-contact mode, S Mode, 2.0 W, 50 pps, direction of the tip 45 degrees to the gum surface. The aim of this procedure was to dehydrate the surface of the connective tissue and by consequence melting the nerve endings, which in the end leads to a reduction or absence of postoperative pain. This method is also referred to as “laser bandage”.

The patient was prescribed saline mouthwash three times daily for one week, as well as application of vitamin E three times daily for seven days and paracetamol 500 mg, two tablets every eight hours in case of pain. The patient was advised to avoid hot meals during the first couple of days after surgery.

No infection or significant postoperative complications, such as pain or bleeding, were encountered. The patient was reviewed two, four and seven days after the procedure (Figs. 6–8). The fifteen-month follow-up showed no signs of recurrence of the pigmentation.

Discussion

Numerous modalities for depigmentation have been used and described in the literature. First, removing pigmented layers can be performed by using chemical methods or surgical methods such as surgical scalpel technique, surgical abrasion, cryosurgery, electrosurgery and laser.

Chemical methods are not recommended because the chemical action cannot be restricted to the oper-
The scalpel technique is the most economical procedure compared to other methods requiring a more sophisticated armamentarium. However, this technique causes unpleasant bleeding during and after the operation, and it is necessary to cover the surgical site with periodontal dressing for seven to ten days.

Abrasion involves eliminating the epithelium of pigmented areas using a round diamond bur in a high-speed handpiece with copious irrigation. The use of a large-size diamond bur is recommended, because small burs do not smooth surfaces easily.

Cryosurgery is a treatment method in which the tissue is destroyed by rapid freezing as described by Tal et al. It can be followed by considerable swelling, and it is accompanied as well by increased soft tissue destruction because of its uncontrolled depth of penetration. Electrosurgery has its own limitations because of its repetitive and prolonged use, provoking heat accumulation and undesired tissue destruction.

The documented advantages of lasers for depigmentation consist of removing the melanin pigmentation by a less invasive procedure in order to eliminate a thin layer of epithelium, less bleeding during the procedure, reduced infection, swelling and scarring, decreased postoperative pain, a fast healing process and increased patient satisfaction regarding aesthetics. The Er:YAG laser used in this case report produced the desired results efficiently. The patient was pleased with the result, which is the definitive objective of any treatment accomplished.

Yet, there is no scientific evidence to establish that laser depigmentation is superior to scalpel depigmentation. On the other hand, techniques masking pigmented gingival from less pigmented gingival areas can be done using free gingival grafts or acellular dermal matrix allografts.

Conclusion

Considering the results of this case report, the depigmentation procedure was successful and the patient was satisfied. It may be concluded that the application of Er,Cr:YSGG laser appears to be secure and efficient for the treatment of gingival melanin pigmentation.
