Thanks to minimally invasive techniques, such as ultrasonic surgery and the availability of reliable restorative materials, the surgical revision and rehabilitation of endodontically treated teeth have a significantly better prognosis than only 10 years ago. Apical resection is a challenging surgical procedure not least because of the limited accessibility of the surgical field. Instrumentation of an apical resection case therefore requires a surgical technique that is as simple as it is safe and ergonomic.

This report presents two clinical cases in illustrating a system for applying retrograde endodontic filling materials that has proven a consistently viable option in our clinical practice.

**Case No. 1**

A 34-year-old male patient presented at our clinic for the first time. The orthopantomogram (OPG) yielded an accidental finding of apical translucencies at teeth #14, 36 and 46, which had been insufficiently treated endodontically. Clinically, these translucencies were asymptomatic and diagnosed as instances of chronic apical periodontitis or apical osteitis (Fig. 1).

Together with the patient, we planned for an apical resection of tooth #36 in conjunction with a retrograde root-canal filling with subsequent removal of the non-salvageable teeth #16 and 46. Following extensive consultation and patient education, surgery was performed under local infiltration anaesthesia. With our protocol, block anesthesia is unnecessary in 98 percent of all surgical interventions in the mandible, and dispensing with it minimizes the risk of iatrogenic nerve damage.

An incision was performed in the marginal gingiva, with a mesiodistal relief incision, fol-
The CALASEPT Endo Line

CALASEPT PLUS
* More than 41% calcium hydroxide
* Optimal calcium release
* Strong bactericidal effect pH 12,4
* Flexi-tip for precise and deep application

NEW

CALASEPT® EDTA
EDTA Solution 17%
* Lubricating capacity, to minimize file fractures
* Removes smear layer and inorganic substances
* Increase the adhesion to filling materials
* Bottle neck with luer adaptor for easy filling of syringe

CALASEPT CHX
Chlorhexidine Solution 2%
* Final Irrigation after EDTA and Sodium Hypochlorite
* Discontinues erosion of canal walls
* Bactericidal
* Bottle neck with luer adaptor for easy filling of syringe

lowed by preparation of a full flap for adequate access to the surgical site. Using the Piezotome 2 (Acteon), a buccal bone window of adequate depth was prepared to gain access to the apical region at tooth #36 in order to perform the apical resection.

It is helpful for the preparation to provide for undercuts in order to facilitate subsequent removal of the bone block. As no rotary instruments were used, and because ultrasonic surgical instruments have a vaso-constrictor effect, the surgical field remained impressively free of bleeding and afforded a clear view of the site. The bone block was stored in Ringer’s solution to facilitate subsequent repositioning (Fig. 2). The root apices were then exposed and ultrasonically removed (Fig. 3).

After apical resection, our protocol called for thorough removal of all soft tissue using instruments, followed by complete decontamination of the cyst lumen using a diode laser.

Care had to be taken to ensure that the laser tip did not make direct contact with the bone. Retrograde preparation of the root canals was also performed ultrasonically, which only takes a few seconds when using the Piezotome 2.

Following chlorhexidine-digluconate and sodium-hypochlorite rinses, the retro-prepared root canals were dried with paper points. In our clinic, we have had excellent success with the MAP (Micro-Apical Placement) retro system (PDSA), which has been on the market for many years (Fig. 4). The system comes in a sterilizable metal container (Fig. 5).

The triple-angled endo tips (Fig. 6) greatly simplify the uptake and application of the material, with the syringe facilitating “injection” (retrograde obturation) of the root canal to a depth of several millimeters. This well-targeted application of the restorative material keeps the surgical field open (Fig. 7).

On application of ProRoot MTA (DENTSPLY Maillefer), the material was allowed to set, the cross-section surface of the resected area was smoothed and polished, the resection lumen was filled with a quick-hardening bone cement (VitalOs, PDSA), and the bone block was returned to its place (Fig. 8).

The post-operative radiograph shows the site following apical resection and retrograde root filling (Fig. 9).

The patient was prescribed Amoxicillin 750 mg and Ibuprofen 600 mg post-operatively, as well as Arnica C30 to prevent swelling. Post-operative healing was uncomplicated and the sutures could be removed after eight days. Swelling was minimal, and the patient reported virtually no post-operative pain.

NEW!
A 65-year-old female patient presented with an apical resection on tooth #14 that had been performed alio loco five years before. The patient was looking for help because the site had become infected again. She reported pain at tooth #14 on occlusal contact and percussion. A local digital radiograph clearly showed the area of apical resection, the two root-canal fillings, and a cystic peri-apical radiolucency (Fig. 10). Because this was a surgical re-entry case, the same incision technique was used as chosen by the primary treatment provider, i.e. a crescent-shaped incision as described by Pichler (Fig. 11). The procedure was otherwise the same as in Case No. 1. Following retrograde ultrasonic preparation (Fig. 12), ProRoot MTA was mixed to a working consistency and applied using the MAP System (Figs. 13, 14). This clean and efficient application mode and controlled handling shortened the surgical procedure and reduced post-operative complaints (Fig. 15). The post-operative radiograph (Fig. 16) shows an efficient retrograde filling of both root canals following revision of tooth #14. Owing to a projection artifact, the restorative appeared beside the canals, when it was in fact clinically located exactly within.

**Conclusion**

Apical resection is a routine procedure in our clinic. Thanks to the use of ultrasonic surgery, the surgical laser and the MAP System, this procedure is reliable, predictable and simple, and we have preserved the natural teeth of many patients. Being an oral implantologist myself, I do not perceive anything contradictory in looking at these treatment methods; rather, apical resection is a complementary treatment mode and an attempt to preserve teeth over the longer term that would otherwise be considered lost.
