Bioactive endodontic obturation: Combining the new with the tried and true

MTA Fillapex and Continuous Wave of Condensation

**Author** Gary Glassman, DDS, FRCD(C)

The triad of biomechanical preparation, chemotherapeutic sterilization and three-dimensional obturation is the hallmark of endodontic success.\(^1,2\)

The obturation of root canal systems represents the culmination and successful fulfillment of a series of highly integrated procedural steps (Figs. 1a, b). Although the excitement associated with capturing complicated root canal anatomy is understandable, scientific evidence should support this enthusiasm. Moving heat-softened obturation materials into all aspects of the anatomy is dependent on eliminating pulpal tissue, the smear layer and related debris and bacteria and their byproducts, when present. To maximize obturation potential, clinicians would be wise to direct treatment efforts toward shaping canals and cleaning root canal systems.\(^2–4\)

Shaping facilitates three-dimensional cleaning by removing restrictive dentin, allowing a more effective volume of irrigant to penetrate, circulate and potentially clean into all aspects of the root canal system (Fig. 2). Well-shaped canals result in a tapered preparation that serves to control and limit the movement of warm gutta-percha during obturation procedures. Importantly, shaping also facilitates 3-D obturation by allowing pre-fit pluggers to work deep and unrestricted by dentinal walls and move thermosoftened obturation materials into all aspects of the root canal system. Improvement in obturation potential is largely attributable to the extraordinary technological advancements in shaping canals and cleaning and filling root canal systems.\(^4–6\)

In the article “Filling Root Canals in Three Dimensions,”\(^7\) Dr. Herb Schilder stated that while there was merit in all obturation techniques available at that time, “when used well ... vertical condensation of warm gutta-percha produces consistently dense, dimensionally stable, three-dimensional root canal fillings.” This landmark article gave birth to a paradigm shift in not only a variety of warm gutta-percha techniques, but in a new approach to cleaning and shaping canals, as well as irrigation protocols.\(^8\)

In addition to the classic “Schilder technique” of obturation, there is Steve Buchanan’s “Continuous Wave of Condensation” technique⁹ and variations thereof. Vertical condensation of gutta-percha is now one of the most-trusted obturation methods of our time. It is taught in most of the graduate endodontic programs in North America and in a growing number of undergraduate programs as well. Its success rate is well documented."¹⁰

This article will feature the Elements Obturation Unit (Axis/SybronEndo, Coppell, Texas) that may be used to fill root canal systems (Fig. 3a) using the Continuous Wave of Condensation technique and a new mineral trioxide aggregate-based endodontic sealer that is biocompatible and bioactive, called MTA Fillapex (MTA-F; Angelus, Londrina, Brazil) (Fig. 3b).

Mineral trioxide aggregate was developed at Loma Linda university and in 1998 received approval from the FDA for human use."¹¹,¹²

Since then, MTA has shown excellent biological properties in several in vivo and in vitro studies."¹³-¹⁸ In cell culture systems, for example, MTA has been shown to enhance proliferation of periodontal ligament fibroblasts,"¹⁵ to induce differentiation of osteoblasts"¹⁶,¹⁷ and to stimulate mineralization of dental pulp.

In an effort to expand its applicability in endodontics, MTA-based root canal sealers have been proposed, such as MTA Fillapex."¹⁹-²²

MTA Fillapex is an endodontic sealer that combines the proven advantage of MTA with a superior canal obturation product. Its formulation in the paste/paste system allows a complete filling of the entire root canal, including accessory and lateral canals. MTA, present in the composition of MTA Fillapex, is more stable than calcium hydroxide, providing constant release of calcium ions for the tissues and maintaining a pH that elicits antibacterial effects. The tissue recovery and the lack of inflammatory response are optimized by the use of MTA and disalicylate resin. The product is eugenol-free and will not interfere with adhesive procedures inside the root canal.

The two-paste system contains tricalcium silicate, dicalcium silicate, calcium oxide and tricalcium aluminate, a salicylate resin, a natural resin and bismuth oxide as a radiopacifying agent. The combination of these components has been shown to have bioactive potential in its ability to stimulate nucleation sites for the formation of apatite crystals in human osteoblast-like cell culture."²²

The two pastes of MTA Fillapex are mixed in equal volumes and dispensed on a glass slab. Its average working time is 35 minutes, with an average setting time of 130 minutes.

The chemical reaction that promotes setting in MTA Fillapex is not a polymerization reaction between pastes but a complexation reaction. The complexation reaction is an autocatalytic process. A chain reaction is initiated by water molecules in the external medium that has an intrinsic process of self-acceleration. The complexation reaction is also a chelation reaction where Ca(OH)₂ contacts the disalicylate resin, resulting in the entrapment of calcium ions in the compound. In addition to salicylate, Ca(OH)₂ is fundamental. The major source of Ca(OH)₂ responsible for the MTA Fillapex reaction is from the hydration of free CaO, which is in high concentration in the formula. It is therefore concluded that the moisture present in the dentin tubules hydrates free CaO, forming Ca(OH)₂, which will react with the salicylate and promote the setting."²³

The Continuous Wave of Condensation technique

This technique allows a single-tapered electric heat plugger to capture a wave of condensation at the orifice of a canal and ride it, without release, to the apical extent of downpacking in a single, con-
Continuous movement. Because the tip moves through a viscosity-controlled material into a tapered-like canal form, the velocity of the thermosoftened gutta-percha and sealer moving into the root canal system actually accelerates as the downpacking progresses, moving softened gutta-percha into extremely small ramifications (Figs. 4a, b).

The continuously tapered root canal preparation facilitates the fit of a suitably sized gutta-percha cone, preferably fine-medium or medium. A clever tool to assist with the cone fit, especially if you choose not to use pre-sized cones or prefer non-standardized cones, is a gutta-percha gauge such as the Tip Snip (Axis/SybronEndo, Coppell, Texas) (Fig. 5). This allows you to customize a non-standardized or tapered cone to a precise apical diameter. The master cone is fit in a fluid-filled canal to more closely simulate the lubrication effect that sealer will provide when sliding the buttered master cone into the prepared canal.

Further, the master cone should be able to be inserted to the full working length and exhibit apical tugback upon removal. It is simple to fit a master cone into a patent, smoothly tapered and well-prepared canal.

The intimacy of diametrical fit between the cone and the canal space is confirmed radiographically (Fig. 6). The cone is then trimmed about 0.5 to 1 mm from radiographic terminus, so that its most apical end is just short of the working length to accommodate vertical movement of the vertically condensed gutta-percha cone.

The System-B 0.06 or 0.08 taper, 0.5 mm plugger should fit to within 4 to 6 mm from most canal termini and is pre-fit to its binding point in the canal, and the rubber stop is adjusted adjacent to a reference point (Fig. 7).

Difficulties in achieving adequate plugger depth are because of deficient deep shape in the canal preparation (inadequate enlargement 3 to 4 mm shy of the terminus).

Stainless-steel Buchanan pluggers (Axis/SybronEndo, Coppell, Texas) are pre-fit into the canals to their binding point. Rubber stoppers are adjusted on these pluggers to the occlusal reference point, corresponding to 2 mm short of the apical binding point. These pluggers are placed aside to be used later in the backfill phase of canal obturation (Fig. 8).

**Sealer and master cone placement**

MTA Fillapex (Fig. 9a) can be used for the warm gutta-percha with vertical condensation technique and affords several advantages.23

The presence of MTA in the formula along with its calcium ion release allows the formation of new tissue, including root cementum without causing an inflammatory reaction. Perfect radiographic visualization is possible because of its high radiopacity, and its excellent flow properties make MTA Fillapex suitable to penetrate and fill lateral and accessory canals. Upon setting, MTA Fillapex expands, thereby providing an excellent seal of the root canal, avoiding the penetration of tissue fluids and/or bacterial recontamination. It is available in a two-paste system, which allows easy handling, insertion and adequate working time to be used by both specialists and/or general practitioners.

‘As the health of the attachment apparatus associated with endodontically treated teeth becomes fully understood and completely appreciated, the naturally retained root will be recognized as the ultimate dental implant.’
Penetrate Lateral Canals and Isthmus Better Than Needle Irrigation

CanalPro™
Ultrasonic Irrigator

- Distributes and ultrasonically activates sodium hypochlorite to increase debridement of lateral canals and isthmuses

Benefits of Continuous Ultrasonic Irrigation:
- Removes significantly more debris from narrow isthmuses better than conventional needle irrigation*
- Significantly increases the penetration of irrigation solutions into lateral canals**

technique of obturation

If retreatment is necessary it is easily removed particularly when used with GP points.

The amount of sealer used in this obturation technique should be minimal.

The radicular portion of the master cone is lightly buttered with sealer and gently swirled as it is slowly slid to length. Placing the master cone in this manner will serve to more evenly distribute sealer along the walls of the preparation and, importantly, allow surplus sealer to harmlessly vent coronally. To be confident that there is sufficient sealer, the master cone is removed and its radicular surfaces inspected to ensure it is evenly coated with sealer. If the master cone is devoid of sealer, then simply re-butter and re-insert this cone to ensure there is sufficient sealer present. When the master cone is evenly coated with sealer and fully seated, obturation can commence.

The canal is dried and the master cone is cemented in the canal with sealer (Fig. 9b).

The System-B handpiece is activated by depressing the button with a gloved finger. The tip will heat instantly, and the LED indicator on the handpiece will illuminate. The tip will remain heated only as long as the button is depressed. A “time-out” feature assists the clinician by shutting off the energy to the tip after four seconds. This will aid in avoiding overheating of the tooth and/or tissue. The handpiece will need to be reactivated to resume heating beyond the preset duration.

The master cone is seared at the orifice of the canals with the activated System-B plugger and then gently “seated” with a larger stainless-steel Buchanan plugger. The plugger is driven through the center of the gutta-percha in a single motion (about one to two seconds), to a point about 3 to 4 mm shy of its apical binding point (Figs. 10, 11).

While maintaining pressure on the plugger, the activation button on the System-B is released and the plugger slows its apical movement as the plugger tip cools (about one second) to within 2 mm from its apical binding point. After the plugger stops short of its binding point, apical pressure on the plugger is sustained until the apical mass of gutta-percha has set (five to 10 seconds), to prevent any shrinkage that occurs upon cooling (Fig. 12).

Separation burst

After the apical mass has set, the activation button on the System-B is depressed again, for a one-second surge of heat. Pause for one second after this separation burst, and then remove the heated plugger and the middle and coronal gutta-percha, leaving behind the 4 to 6 mm apical plug of gutta-percha (Figs. 13, 14). Because these pluggers heat from their tips, this separation burst of heat allows for quick, sure severance of the plugger from the already condensed and set apical mass of gutta-percha, minimizing the possibility of pulling the master cone out. Be certain to limit the length of this heat burst, as the goal is separation from the apical mass of gutta-percha without reheating.

Clinicians must be very alert during the first second of the downpack that the binding point is not reached before completion of the downpack. If heat is held for too long, the plugger drops to its binding point in the canal and then cannot maintain condensation pressure on the apical mass of gutta-percha during cooling, possibly allowing it to pull away from the canal walls. If binding length is reached by mistake, the heat plugger should be removed immediately, and the small end of the nickel-titanium end of a Buchanan hand plugger (Sybron Endo, Orange, Calif.) should be used to condense the apical mass of gutta-percha until set.

Backfilling

The Elements Obturation Unit (Fig. 3a) has an extruder handpiece that accommodates dispos-

The technique of obturation

Technique

The master cone is cemented in the canal with sealer.

Figs. 10, 11. With the activation button depressed on the System B handpiece, the pre-fit, preheated plugger is smoothly driven through the mass of gutta-percha to within 4 to 6 mm of the binding point.

Figs. 12. The activation button should be released once within 3 to 4 mm of the apical binding point. The plugger should slow and stop within 2 mm short of the binding point. Apical pressure is maintained for a full 10-second “sustained” push to prevent the cooling gutta-percha mass from shrinking.

Figs. 13, 14. The System-B activation button is depressed for one second then released. The plugger is held in position for one second after the button is released, and the plugger is removed with the down pack surplus of gutta-percha, leaving the apical seal intact. All portals of exit may be sealed, primarily with gutta-percha or a combination of gutta-percha and sealer, and the canal is ready for backfilling.

Restoration of the endodontically treated tooth

To ensure a seamless link between the root canal procedure and the permanent restoration of the tooth, immediate restoration is the very best policy to protect the hard work you have just accomplished with the previous steps. Where temporization is necessary, ensuring a coronal seal is crucial to long-term success. Taking a few minutes to lay down an effective coronal seal protects your three-dimensionally obturated root canal from coronal leakage.

The future

With each improvement and modification of the technical limitations of the technique, the thermosoftened millennium will continue to expand the horizons of endodontic success and elevate the standard of care and pursuit of excellence in clinical treatment materials.

As the health of the attachment apparatus associated with endodontically treated teeth becomes fully understood and completely appreciated, the naturally retained root will be recognized as the "ultimate dental implant." When properly performed, endodontic treatment is the cornerstone of restorative and reconstructive dentistry.
