Since bioceramic technology was introduced to endodontics, the response has been exceptional. As more and more practitioners have thought through the process, they have been able to see not only the clear benefits of this technology in endodontics, but they are now asking how this technology can be applied to other aspects of dentistry. The application of bioceramic technology has not only changed endodontics both surgically and non-surgically, it has also begun to change the way we treatment plan our patients. As a result of bioceramic technology, we now have the ability to save more teeth in a predictable fashion, while, in addition, improving their long-term prognosis. The option of “saving the natural dentition” is now back on the table.

However, before we investigate specific techniques, we must first ask ourselves is, “What are bioceramics?” Bioceramics are ceramic materials specifically designed for use in medicine and dentistry. They include alumina and zirconia, bioactive glass, glass ceramics, coatings and composites, hydroxyapatite and resorbable calcium phosphates.1,2

There are numerous bioceramics currently in use in both dentistry and medicine, although more so in medicine. Alumina and zirconia are among the bio-inert ceramics used for prosthetic devices. Bioactive glasses and glass ceramics are available for use in dentistry under various trade names. Additionally, porous ceramics such as calcium phosphate-based materials have been used for filling bone defects. Even some basic calcium silicates such as ProRoot MTA (DENTSPLY) have been used in dentistry as root repair materials and for apical retrofills.

Although employed in both medical and dental applications, it is important to understand the specific advantages of bioceramics in dentistry and why they have become so popular. Clearly the first answer is related to physical properties. Bioceramics are exceedingly biocompatible, non-toxic, do not shrink, and are chemically stable within the biological environment. Additionally, and this is very important in endodontics, bioceramics will not result in a significant inflammatory response if an over fill occurs during the obturation process or in a root repair. A further advantage of the material itself is its ability (during the setting process) to form hydroxyapatite and ultimately create a bond between dentin and the filling material. A significant component of improving this adaptation to the canal wall is the hydrophilic nature of the material. In essence, it is a bonded restoration. However, to fully appreciate the properties associated with the use of bioceramic technology, we must understand the hydration reactions involved in the setting of the material.
_EndoSequence BC sealer setting reactions_

The calcium silicates in the powder hydrate to produce a calcium silicate hydrate gel and calcium hydroxide. The calcium hydroxide reacts with the phosphate ions to precipitate hydroxyapatite and water. The water continues to react with the calcium silicates to precipitate additional gel-like calcium silicate hydrate. The water supplied through this reaction is an important factor in controlling the hydration rate and the setting time as following:

The hydration reactions (A, B) of calcium silicates can be approximated as follows:

\[
2[3\text{CaO} \cdot \text{SiO}_2] + 6\text{H}_2\text{O} \rightarrow 3\text{CaO} \cdot 2\text{SiO}_2 \cdot 3\text{H}_2\text{O} + 3\text{Ca} (\text{OH})_2 \tag{A}
\]

\[
2[2\text{CaO} \cdot \text{SiO}_2] + 4\text{H}_2\text{O} \rightarrow 3\text{CaO} \cdot 2\text{SiO}_2 \cdot 3\text{H}_2\text{O} + \text{Ca} (\text{OH})_2 \tag{B}
\]

The precipitation reaction (C) of calcium phosphate apatite is as follows:

\[
7\text{Ca(OH)}_2 + 3\text{Ca} (PH)_2 \rightarrow \text{Ca}_3 (\text{PO}_4)_2 \cdot \text{OH} + 12\text{H}_2\text{O} \tag{C}
\]

For clinical purposes (in endodontics), the advantages of a premixed sealer should be obvious. In addition to a significant saving of time and convenience, one of the major issues associated with the mixing of any cement, or sealer, is an insufficient and non-homogenous mix. Such a mix may ultimately compromise the benefits associated with the material. Keeping this in mind, a new premixed bio ceramic sealer has been designed that hardens only when exposed to a moist environment, such as that produced by the dentinal tubules.

But, what is it specifically about bio ceramics that make them so well suited to act as an endodontic sealer? From our perspective as endodontists, some of the advantages are: high pH (12.8) during the initial 24 hours of the setting process (which is strongly anti-bacterial); they are hydrophilic, not hydrophobic; they have enhanced biocompatibility; they do not shrink or resorb (which is critical for a sealer-based technique); they have excellent sealing ability; they set quickly (three to four hours); and they are easy to use (particle size is so small it can be used in a syringe).

The introduction of a bioceramic sealer (EndoSequence BC Sealer, Brasseler) allows us, for the first time, to take advantage of all the benefits associated with bio ceramics but to not limit its use to merely root repairs and apical retrofills. This is only possible because of recent nanotechnology developments; the particle size of BC Sealer is so fine (less than two microns), it can actually be delivered with a 0.012 capillary tip (Fig. 1).

This material has been specifically designed as a non-toxic calcium silicate cement that is easy to use as an endodontic sealer. This is a key point. In addition to its excellent physical properties, the purpose of BC Sealer is to improve the convenience and delivery method of an excellent root canal sealer, while simultaneously taking advantage of its bioactive characteristics (it utilizes the water inherent in the dentinal tubules to drive the hydration reaction of the material, thereby shortening the setting time).

As we know, dentin is composed of approximately 20 per cent (by volume) water, and it is this water that initiates the setting of the material and ultimately results in the formation of hydroxyapatite. Therefore, if any residual moisture remains in the canal after drying, it will not adversely affect the seal established by the bio ceramic cement. This is very important in obturation and is a major improvement over previous sealers. Furthermore, its hydrophilicity, small particle size and chemical bonding to the canal walls also contribute to its excellent hydraulics. But there is another aspect to sealer hydraulics. That is the shape of the prepared canal itself.

Actually, it all begins with the file. To be more specific, it all begins with the specific preparation created by the file—a constant taper preparation. When using the EndoSequence technique, we can create either a 0.04 constant taper preparation or a 0.06 taper. The real key is the constant taper preparation, because when accomplished it now gives us the ability to create predictable, reproducible shapes. A variable taper preparation is not recommended because its lack of shaping predictability (and its corresponding lack of reproducibility) will lead to a less than ideal master cone fit. This lack of endodontic synchronicity is why all variable taper preparations are associated with the overly expensive and more time consuming thermoplastic techniques.
Knowing in advance what the final shape (constant taper preparation) will be is a tremendous advantage in creating superior hydraulics. Then add in the feature of laser verified paper points and gutta-percha cones, and we now start to develop a system where everything matches (true endodontic synchronicity).

This concept of having everything match is so important because it allows us, for the first time, to perform rotary endodontics in a truly conservative fashion and to be able to use a hydraulic condensation technique. Furthermore, when used in conjunction with the EndoSequence filing system, this becomes a synchronized hydraulic condensation technique. This has tremendous implications for the tooth as evidenced by a recent study published in the Journal of Endodontics. The purpose of this study was to evaluate and compare the fracture resistance of roots obturated with various contemporary-filling systems. The investigators (Ghoneim, et. al.) instrumented 40 single-canal premolars using 0.06 taper EndoSequence files. The teeth were then obturated using four different techniques. Group I used a bioceramic sealer iRoot SP (iRoot SP is BC Sealer in Europe) in combination with ActiV GP cones (Brasseler) while Group II used the bioceramic sealer with regular gutta-percha. Group III utilized ActiV GP sealer plus ActiV GP cones and Group IV employed ActiV G sealer with conventional gutta-percha cones. All four groups were obturated using a single cone technique. Ten teeth were left unprepared and these acted as a negative control for the study.

Following preparation and obturation, all the teeth were embedded in acrylic molds and then subjected to a fracture resistance test in which a compressive load (0.5 mm/min) was applied until fracture. Subsequently, all data was statistically analyzed using the analysis of variance model and the Turkey post hoc test.

Then results generated were quite remarkable. It was demonstrated that the significantly highest fracture resistance was recorded for both the negative control and Group I (bioceramic sealer/ActiV GP cone) with no statistical difference between them. The lowest reported value was in Group IV, which employed ActiV GP sealer in combination with regular gutta-percha cones. The conclusion of this study was that employing a bioceramic sealer (such as BC Sealer) is very promising in terms of strengthening the residual root and increasing the in vitro fracture resistance of endodontically treated teeth. This is a very significant finding, especially regarding the long term retention of an endodontically treated tooth.

In this particular study, the bioceramic sealer performed best when combined with ActiV GP cones. In fact, bonding will occur between the bioceramic sealer and the ceramic particles in the ActiV GP cones as well as to the bioceramic particles present in the new bioceramic coated cones (BC cones). The technique of achieving a true bond between the root canal wall and the master cone (as a result of creating endodontic synchronicity and advanced material science) is known as synchronized hydraulic condensation.

_Synchronized hydraulic condensation_

The technique with this material is quite straightforward. Simply remove the syringe cap from the EndoSequence BC Sealer syringe. Then attach an Intra Canal Tip of your choice to the hub of the syringe. The Intra Canal Tip is flexible and can be bent to facilitate access to the root canal. Also, because the particle size has been milled to such a fine size (less than 2 microns), a capillary tip (such as a 0.012) can be used to place the sealer.

Following this procedure, insert the tip of the syringe into the canal no deeper than the coronal one third. Slowly and smoothly dispense a small amount of EndoSequence BC Sealer into the root canal. Then remove the disposable tip from the syringe and proceed to coat the master gutta-percha cone with a thin layer of sealer. After the cone has been lightly coated, slowly insert it into the canal all the way to the final working length. The synchronized master gutta-percha cone will carry sufficient material to seal the apex.

The precise fit of the EndoSequence gutta-percha master cone (in combination with a constant taper preparation) creates excellent hydraulics and, for that reason, it is recommended that the practitioner use only a small amount of sealer. Furthermore, as with all obturation techniques, it is important to insert the master cone slowly to its final working length. Moreover, the EndoSequence System is now available with bioceramic coated gutta-percha cones. So in essence, what we can now achieve with this technique is a chemical bond to the canal wall, as a result of the hydroxyapatite that is created during the setting reaction of the bioceramic material and we also have a chemical bond between the

Think about what we have just accomplished. We are now doing root canals in a manner that truly is easier, faster and better. As further evidence of this technique, we asked Dr Adam Lloyd, the chairman of the Department of Endodontics at the University of Tennessee, to share the results of a study recently conducted at the University of Tennessee.7

_Materials and methods_

Sixteen recently extracted human molars were mounted on individual stubs and underwent an initial high spatial resolution CT scan prior to any treatment. Following biomechanical crown-down canal preparation to an apical matrix of 35/0.04 and ultrasonic irrigation with 6 per cent sodium hypochlorite, each sample was scanned a second time. Obturation was completed using a single matched gutta-percha cone and EndoSequence BC sealer. The coronal 4 mm of the gutta-percha was thermo-softened and compacted vertically. Subsequent to canal obturation, a third scan was made.

Scanning of the specimens was performed (Actis 150/130, Varian Medical Systems) with a 180-degree rotation around the vertical axis and a single rotation step of 0.9 degree with a cross-sectional pixel size of approximately 24 µm. All three backscatter projections were aligned post-processing with sub-voxel accuracy at 92 per cent CI in VG Studio Max 2.1 (Volume Graphics GmbH) and manipulated to create regions of interest for each of the scans.

_Results_

Analysis of volume occupied by sealer in relation to total original canal volumes was found to be extremely high with a mean of 97 per cent ± 2.8, much higher than reported previously using studies on canal surface area occupancy of material, with 75 per cent of samples occupied at the ≥ 95 per cent level (Figs. 2a, 2b).
While the properties associated with bioceramics make them very attractive to dentistry, in general, what would be their specific advantage if used as an endodontic sealer? From our perspective as endodontists, some of the advantages are: enhanced biocompatibility, possible increased strength of the root following obturation, high pH (12.8) during the setting process which is strongly antibacterial, sealing ability related to its hydophilicity, and ease of use. Furthermore, the bioceramic sealer does not shrink upon setting (it actually expands 0.002 per cent) and once it is fully set, the material will not resorb.

The cases pictured in Figs. 3a through 5c demonstrate the excellence of this technique.

**Retreatment of bioceramics**

Bioceramic sealer cases are definitely retreatable yet the issue of retracting these cases (and all the associated misinformation) is not unlike that of glass ionomer. Historically there has been confusion about retracting glass ionomer endodontic cases (glass ionomer sealer is definitely retreatable when used as a sealer) and, similarly, there has been confusion concerning the retractability of bioceramics. The key is using bioceramics as a sealer, not as a complete filler. This is why endodontic synchronicity is so important and again, why the use of constant tapers makes so much sense (it minimizes the amount of endodontic sealer thereby facilitating retreatment).

The technique itself is relatively straightforward. The key in retracting bioceramic cases is to use an ultrasonic with a copious amount of water. This is particularly important at the start of the procedure in the coronal third of the tooth. Work the ultrasonic (with lots of water) down the canal to approximately half its length. At this point, add a solvent to the canal (chloroform or xylol) and switch over to an Endo-Sequence file (#30 or 35/0.04 taper) run at an increased rate of speed (1,000 RPM). Proceed with this file, all the way to the working length, using solvent when indicated. An alternative is to use hand files for the final 2-3 mm and then follow the gutta-percha removal with a rotary file to ensure synchronicity.

The case pictured in Figs. 6a and 6b demonstrates the retreatment of BC Sealer.

**Bioceramics as a root repair material**

We are all familiar with the success of MTA (mineral trioxide aggregate) as a root repair and apico retrofilling material. Furthermore, we realize that because MTA is a modified Portland cement, it has some limitations in terms of handling characteristics. It does not come premixed (and therefore must be mixed by hand), is difficult to use on retrofills, and has such a large particle size that it cannot be extruded through a small syringe. Yet it has a number of favorable characteristics including a pH of 12.5, which is significantly anti-bacterial. However, in lieu of a Portland cement-based material, we now have available a medical grade bioceramic repair material.

This new repair material is, in fact, the Endo-Sequence Root Repair material, which comes either premixed in a syringe (just like BC Sealer) or as a premixed putty (Fig. 7). This is a tremendous help not just in terms of assuring a proper mix but also in terms of ease of use. We now have a root repair material with an easy and efficient delivery system. This is a key development and a serious upgrade. This allows many clinicians, not just specialists, to take advantage of its properties.
EndoSequence Root Repair material specifically has been created as a white premixed cement for both permanent root canal repairs and apico retrofillings. As a true bioceramic cement, the advantages of this new repair material are its high pH (pH >12.5), high resistance to washout, no-shrinkage during setting, excellent biocompatibility, and superb physical properties. In fact, it has a compressive strength of 50–70 MPa, which is similar to that of current root canal repair materials, ProRoot MTA (DENTSPLY) and BioAggregate (Diadent). However, a significant upgrade with this material is its particle size, which allows the premixed material to be extruded through a syringe rather than inconsistent mixing by hand and then placement with a hand instrument.

The Clinicians Report (November 2011) published findings on EndoSequence Root Repair Material. Some of its noted advantages as a root repair material were:  
- easier to use and place than previous similar products,  
- good dispenser (tip/syringe) for easy dispensing,  
- radiopaque,  
- multiple uses for a variety of clinical conditions,  
- no mixing required.

Furthermore, their final conclusion was that 95 per cent of 19 CR Evaluators stated that they would incorporate EndoSequence Root Repair Material into their practice. Ninety-five percent rated it excellent or good and worthy of trial by colleagues.

Another significant piece of research was published in the Journal of Endodontics, where a research team investigated the antibacterial activity of EndoSequence Root Repair material against Enterococcus faecalis. The aim of this study was to determine whether EndoSequence Root Repair material either in its putty form or as a syringeable paste possessed antibacterial properties against a collection of Enterococcus faecalis strains. As a standard, they compared the ESRRM to MTA. Their conclusion was, ESRRM, both putty and syringeable forms and white ProRoot MTA demonstrated similar antibacterial efficacy against clinical strains of E. faecalis.

This research again validated earlier studies that found ESRRM (Putty) and ESSRM (Paste) displayed similar in vitro biocompatibility to MTA. Additionally, other studies found that the ESSRM had cell viability similar to Gray and White MTA in both set and fresh conditions.

Even more significant research was published (January 2012) concerning bioceramics in general. In a comparison of endodontic sealers, it was demonstrated that in various moisture conditions within a root canal, iRoot SP (EndoSequence BC Sealer) outperformed all the other sealers. The conclusion of the study was, “Within the experimental conditions of this in vitro study, it can be concluded that the bond strength of iRoot SP to root dentin was higher than that of other sealers in all moisture conditions.”

As mentioned previously, the bioceramic material to use in surgical cases is the EndoSequence Root Repair Material (RRM). The ESRRM is available in two different modes. There is a syringeable RRM (very similar to the basic BC Sealer in its mode of delivery) and there is also a RRM putty that is both stronger and malleable. The consistency of the putty is similar to Cavit G. The RRM in a syringe is obviously delivered by a syringe tip but the technique associated with the putty is different.

When using the putty, simply remove a small amount from the room temperature jar and knead it for...
or processes involving root repair materials (ESRRM) that not only work well, but are easier to use. Hopefully, this will lead to an increased use of bioceramics in our pediatric patients and help these patients save their teeth. All dentists can benefit from this upgrade in technique.

The technique itself for a direct pulp cap with the bioceramic root repair material is as follows: isolate the tooth under a rubber dam and disinfect the exposure site with a cotton ball and NaOCl. Apply a small amount of the RRM from the syringe or, take a small amount of the RRM putty from the jar, and place this over the exposure area. Then, coat the bioceramic repair material with a composite or glass ionomer restoration. Following the placement of this material, proceed with the final restoration, including etching if required. Single visit direct pulp capping is now here.

Future directions and prosthodontic applications

The future promises to be even more exciting in the world of bioceramics. There will be new fast set (8 to 10 minutes) repair materials introduced, as well as a special bioceramic putty for pediatric use (primary teeth). We have also seen the melding of bioceramic technology into the world of prosthodontic cements, with the introduction of Ceramir Crown & Bridge (Doxa Dental). It is easy to predict that we will see more applications of this technology in different aspects of dental medicine.

In this article, we have introduced a new bioceramic sealer (EndoSequence BC Sealer) that when combined with coated cones offers an exciting new obturation technique (Synchronized Hydraulic Condensation). The properties associated with the new bioceramic sealer also allow us to be more conservative in our endodontic shaping which ultimately leads to the preservation of natural tooth structure. Surgical applications have also been introduced, and cases shown, which demonstrate the remarkable ability of bioceramics. The future is bright for bioceramic technology and even more exciting for dental medicine.

**About the Authors**

**Dr Ken Koch,** received both his DMD and certificate in endodontics from the University of Pennsylvania School of Dental Medicine. He is the founder and past director of the New Program in Postdoctoral Endodontics at the Harvard School of Dental Medicine. Prior to his endodontic career, Koch spent 10 years in the Air Force and held, among various positions, that of chief of prosthodontics at Osan Air Force Base and chief of prosthodontics at McGuire Air Force Base. In addition to having maintained a private practice, limited to endodontics, Koch has lectured extensively in both the United States and abroad. He is also the author of numerous articles on endodontics. Koch is a co-founder of Real World Endo.

**Dr Dennis Brave,** a diplomate of the American Board of Endodontics and a member of the College of Diplomates, received his DDS degree from the Baltimore College of Dental Surgery, University of Maryland and his certificate in endodontics from the University of Pennsylvania. In endodontic practice for over 25 years, he has lectured extensively throughout the world and holds multiple patents, including the VisiFrame. Formerly an associate clinical professor at the University of Pennsylvania, Brave currently holds a staff position at The Johns Hopkins Hospital. Along with having authored numerous articles on endodontics, Brave is a co-founder of Real World Endo.

**Dr Allen Ali Nasseh,** received his MMS degree and Certificate in Endodontics from the Harvard School of Dental Medicine in 1997. He received his DDS degree in 1994 from Northwestern University Dental School. He maintains a private endodontic practice in Boston (Microsurgicalendo.com) and holds a staff position at the Harvard’s postdoctoral endodontic program. Nasseh is the endodontic editor for several dental journals and periodicals and serves as the Alumni Editor of the “Harvard Dental Bulletin.” He serves as the Clinical Director of Real World Endo.

The authors may be contacted via their website, www.RealWorldEndo.com, or via email at info@realworldendo.com
